Congress Interested in Agencies' Expansion' of Power • •
A H A Offers Program for U S Employee Health Insurance • •
Both Parties Have Bills for Medical School Assistance • •
Civil Defense Proposes Longer Care for Thermo nuclear Victims • •

STUDY ORDERED ON AGENCIES' EXPANSION OF AUTHORITY

A House subcommittee intends to try to find out if executive departments and agencies are broadening their authority through regulations based on and interpretations of laws passed by Congress

It was not possible to learn immediately how extensive the investigation would be However, the subcommittee has authority to continue its study throughout the remainder of the 85th Congress (until adjournment in 1958), it is expected to set up a separate staff, and it is understood to have access to $250,000 in committee funds for this purpose

The study is under direction of Rep Morgan M Moulder (D, Mo), chairman of a subcommittee on legislative oversight of the Committee on Interstate and Foreign Commerce In the health-medical fields, organizations to be investigated include the Federal Trade Commission, Food and Drug Administration, National Institutes of Health, National Science Foundation, and Public Health Service

Announcing the study, Mr Moulder said that the objective is to learn whether the law "has been and is being faithfully executed by the agency in the public interest" and whether the law and the standards contained in it 'have been and are being interpreted by rule, or internal procedures, to enlarge the area of regulation beyond that intended, and to administer it through procedures not intended by the Congress '

Subjects to be considered will include review and analysis of the law and the intent of Congress when it enacted the law the changing circumstances and growth of the field, whether the law s standards can be drafted in more precise terms with a view to reducing administrative discretion, manner in which rules have been applied in practice internal interpretations as distinct from published rules, and enlargement of the area of regulation supported by the agency's own judicial decisions

A H A'S PLAN FOR U S EMPLOYEE HEALTH INSURANCE

The American Hospital Association's revised plan for health insurance for federal employees now is before the House Post Office and Civil Service Committee, after its introduction by Rep Chet Holifield (D, Calif) Under it the 2 million or so U S civilian employees and their dependents, estimated at about the same number, would be eligible for basic health insurance, with the government paying half the cost, and major medical insurance

Collections from the employee would be made through payroll deductions, something the administration has not yet accepted The Civil Service Commission is drafting an administration bill on this subject, but its details have not been made public

In offering the bill, Mr Holifield said "As an instrument for the financing of needed hospital and medical care, voluntary health insurance has brought succor to million upon millions of our citizens and relief from financial pain as well as bodily pain As a result of this movement of prepaying the costs of possible illness, today the price of health protection has become an accepted normal item in the American family budget This is an accomplishment to be listed among the greatest in the advance of health care during your lifetime and mine '

He added 'The basic benefits prescribed by the bill for the two nationwide contracts are more comprehensive and more adequate than those usually available today to Federal employees or members of the general public So far as concerns hospitalized illness, these benefits are comparable to the best industrial contracts existing today"

Under the A H A proposal, the Civil Service Commission would negotiate two types of contract on a nationwide basis

One would offer basic coverage on a service basis for both doctors' in-hospital charges and hospitalization The maximum coverage available in an area would be provided for doctor s charges, but the same hospital coverage would be provided throughout the country

The other nationwide contract would offer basic coverage on an indemnity basis, but the basic hospitalization benefit would have to be sufficient to meet the cost of hospital care On this point Mr Holifield says 'This provision is included because to impose on the employee a portion of the cost of hospitalization in the ordinary case imposes on him a burden that will often prove unreasonably heavy to persons of the income level of most federal employees '

At the same time the employee would be offered payroll deduction facilities to pay for major medical or catastrophic insurance

Employees would have a choice of service or indemnity basic coverage, and they also would be permitted to purchase protection through federal employees association or through group practice arrangements

The U S would contribute a maximum of $2 17 per month for each employee, or $5 42 for employee and family, matching the employee's contribution Thus if the costs of basic insurance for a family came to less than $10 84 per month, the balance of the U S contribution would be applied as matching money to help pay the cost of major medical coverage

It is estimated that the U S would pay about 40% of the total health insurance costs for the employee taking out both basic and major medical insurance

At present it is estimated that federal employees who are enrolled in Blue Cross and Blue Shield pay about $3 50 per month for their own coverage, and $8 90 if families are covered Thus under the A H A plan the employee would pay less for basic and major medical protection than he now pays for basic protection alone

It is expected the Post Office and Civil Service Committee will defer hearings on federal employee health insurance until the administration bill has been introduced (Continued on next page)

'LANOXIN'
brand
DIGOXIN
formerly known as Digoxin 'B W & Co'®

for prompt digitalization and dependable maintenance

Dear Doctor:

The new name for Digoxin 'B. W. & Co.' is 'LANOXIN'. This change will now make it easier for everyone to distinguish digoxin from digitoxin.

Now, simply write...

'Lanoxin' Tablets
0.25 mg or 0 5 mg

to provide the safety and predictability afforded by the uniform potency, uniform absorption, brief latent period and optimum rate of elimination of this crystalline glycoside.

A pure, stable, crystalline glycoside isolated from Digitalis lanata...

Washington News—Continued

DEMOCRATS' BILL ON AID TO MEDICAL AND DENTAL SCHOOLS

Five Democratic senators have jointly introduced a bill for federal aid to medical, dental, and osteopathic schools for construction and equipment The sponsors are Senators Hill (Ala), chairman of the Labor and Welfare Committee, Neely (W Va), Humphrey (Minn), Smathers (Fla), and Kennedy (Mass)

There are some significant differences between this bill and the administration bill, drafted earlier and introduced at the request of Secretary Folsom Here are some comparisons

The administration bill would amend the present three-year 30-million-dollar a year program for research construction grants by increasing the amount to a total of 225 million dollars for use over four years, with the money to help build medical-dental teaching facilities as well as research facilities

The Democrats would leave intact the present research grants program of 30 million dollars a year for three years, and in addition provide 60 million dollars a year for five years to help build medical-dental teaching facilities, for a total of 390 million dollars

Under the administration bill, federal money could not exceed 50% of the project cost The Democrats also call for 50-50 matching, except that the federal government would provide money on a two-to-one basis under two conditions (*a*) if the school gives assurances that the freshman enrollment would be increased by 5% and (*b*) in the case of new schools

To advise on the program, the administration bill would expand the present committee that advises on medical laboratory grants, whereas the Democrats' bill would set up a new 12-man committee, with half of the members from the medical and dental professions

U S CONTROL OF AMPHETAMINES AND BARBITURATES

Legislation that would place controls over the manufacture, distribution, and possession of barbiturates and amphetamines is getting bipartisan support both in and out of Congress Democratic Rep Hale Boggs of Louisiana and Republican representatives John Byrnes of Wisconsin and Antoni Sadlak of Connecticut are sponsoring identical bills

At the outset of the hearings, Chairman Williams said the committee wanted answers to the following questions 1 What are the circumstances that justify these particular drugs being singled out? 2 If there are special circumstances, what is the nature and magnitude of problems created 3 Will provisions in the legislation meet these problems? 4 Are there any alternatives to the solutions suggested in the pending bills?

Secretary Folsom of the Department of Health, Education, and Welfare, estimated it would cost $500,000 to enforce the new law in the first full year of operation

15 MILLION DOLLARS IN WATER POLLUTION CONTROL GRANTS

Federal water pollution control grants totaling $15,212,939 have been awarded during the past two months to 165 municipalities for sewage treatment works The cities and towns will add $49,928,035 of their own funds

These additional grants bring the total awarded since the program's inception last December to $19,096,474, granted to 225 municipalities Congress in last session authorized annual grants of 50 million dollars for 10 years

Maximum grants of $250,000 went to the following 15 areas Mobile, Ala , Richmond, Calif , Norwich, Conn , Ottawa, Ill , Decatur, Ind , Ottumwa, Ill , Owensboro, Ky , Albuquerque, N Mex , Binghamton, N Y , Onondaga Public Works, Syracuse, N Y , Fayetteville, N C , Roseburg, Ore , Casper, Wyo , and Columbia, East Ridge, and Harriman, Tenn

INCREASE IN MENTAL PATIENTS

A report from the National Institute of Mental Health covering 1955 lists 652,000 patients in public hospitals for the prolonged care of the mentally ill, a 1 6% increase over 1954 State hospitals cared for 96 4% and county hospitals 3 6%

In 1955, 3 4 persons were hospitalized for each 1,000 of the population The maintenance expenditure in public hospitals averaged $3 04 per patient a day, totaling $1,107 79 a year

CHANGES IN CIVIL DEFENSE MEDICAL CARE PLAN

The Federal Civil Defense Administration has proposed a new plan providing total medical care for casualties of a thermonuclear attack for as long as one year, in contrast to previous plans concerned only with the first three weeks

Two types of treatment centers are recommended the first for immediate lifesaving measures and the second for more definitive care of the surviving population

A 10-member medical task force committee developed the plan through two logistic exercises last year at Fort Meade and Brooke Army Medical Center that were viewed by representatives of several national health groups

The committee designed the following three-point system

1 Collecting points immediately to the rear of areas of greatest damage where first-aid measures could be taken

2 Emergency treatment station where casualties could be kept on a short-term 'holding basis

3 Civil defense emergency hospitals including substantially the same items as before but having additional equipment and increased capabilities for general medical and surgical care

MISCELLANY

The Internal Revenue Service has decided that a researcher must regard as self-employment income government grants received through an institution, when the institution does not control or direct his research, his status is that of an independent contractor

Of 289 government activities studied as possibly offering unfair competition to business, 50% have been shut down in two years, according to Budget Director Percival F Brundage Testifying before a Senate subcommittee, Mr Brundage said that among the discontinued activities included "20 surgical or orthopedic units,' but he did not say in which agencies or departments they were located

Secretary Folsom presented 40 honor awards to outstanding employees of HEW, including 9 in the Public Health Service

(cont d)

'LANOXIN' continues to offer the same advantages — only the name has been changed.

The full effects of each dose develop quickly to permit rapid appraisal of the need for additional drug. Moreover, the limits of the patient's therapeutic range, which may be reduced in the seriously ill, may be approached with relative safety because toxicity, if it develops, soon abates. For true balance and uniformity of therapeutic effect, prescribe 'LANOXIN' brand Digoxin.

Sincerely,

'B W & Co'

TABLETS 0 25 mg (white) and 0 5 mg (green)

MYST

Squibb Tetracycline Phosphate Complex (Sumycin) + Nystatin (Mycostatin)

Each capsule contains tetracycline phosphate complex equivalent to 250 mg. tetracycline hydrochloride and 250,000 units Mycostatin.

Minimum adult dosage: 1 capsule q.i.d. Bottles of 16 and 100.

ALSO AVAILABLE:

Sumycin Capsules (tetracycline
complex equivalent to 250 mg.
hydrochloride) Bottles of 16
Mysteclin Capsules (250
hydrochloride and
tatin). Bottles of 16 and
Mysteclin Half
tetracycline
units Mycostatin):
Mysteclin
pension containing equivalent
tetracycline hydrochloride
units Mycostatin per 5 cc.):

SQUIBB *Squibb Quality—the Priceless Ingredient*

WHAT IS IT?

the phosphate complex
of tetracycline for initial
antibiotic blood levels ...faster
and higher than ever before

+

antifungal activity of Mycostatin
for added protection against
monilial superinfection

therapy and antifungal prophylaxis

CLINV

WHY SHOULD YOU PRESCRIBE IT?

Because it provides highly effective
broad spectrum antibiotic
therapy for many common infections
and at the same time protects
your patients against the monilial
overgrowth so commonly observed
during therapy with the
usual broad spectrum antibiotics

can you spot the bronchodilator?

Immediate relief is no farther than an arm's reach when your asthma patients carry Norisodrine in the Aerohalor Just one or two inhalations usually abort bronchospasm

Unbreakable and simple to use, the Aerohalor is small enough to fit pocket or purse, handy enough to use anywhere without notice

Side effects? Seldom seen, as long as dosage is accurately adjusted Note, too, that bronchial secretions are not diminished with Norisodrine In fact, you'll often get better drainage as a result of treatment

You might keep a few Aerohalors and some Norisodrine on hand, Doctor Then you can demonstrate, adjust dosage and give your asthmatics ready relief right away

TELEVISION

Sunday, May 12

ABC TV, 4 30 p m EST Medical Horizons will go to the Louisiana State Medical School in New Orleans for a discussion on new virus infections The program is produced in cooperation with the American Medical Association

MAGAZINES

U S News and World Report, March 29, 1957

Eat What You Like But— an interview with Dr Frederick J Stare Harvard School of Public Health

The tremendous upsurge of public interest regarding the relationship between diet and heart disease is reflected by this discussion Questions on cholesterol overweight tension and hard work are answered The article quotes Dr Stare who says in part, Actually I think one could show very carefully that there is a tremendous potential market for the food industry—to get people to eat less so they ll live longer to eat more But nobody wants to be the first to say Eat less of my product

Look, May 14, 1957

X-rays in Color," by Roland H Berg, *Look* Medical Editor

According to this article better diagnosis of certain diseases is made possible by a new method that changes the gray hues of an x-ray to bright colors and enables doctors to detect hidden disease and reduce a patient s exposure to radiation

Better Homes and Gardens, April, 1957

'Leukemia,' by Donald G Cooley

In this article leukemia is explained Some new treatments for the disease are discussed, and Dr William Dameshek is quoted The eventual control of leukemia, though perhaps not close at hand is a real portent for the not too distant future

Should Your Boy Play Organized Baseball? by Kenneth Anderson

Some of the pros and cons of little league baseball are discussed in this article The author suggests that if a boy has an inborn desire to play baseball he should be allowed to do so, but that no boy should be pushed

'Are You *Neglecting Your Child s Eyesight?* by John E Eichenlaub, M D

The author recommends regular eye tests for school age children

Life, April 22, 1957

A Clue in the Studies of Smoking Dangers

According to the article, a waxy substance found in the coating and the pores of tobacco leaves is a major source of cancer-producing tars in cigarette smoke

Redbook, May, 1957

Childbirth Under Hypnosis, by Ruth and Edward Brecher

Many answers to questions on the use of hypnotism in medicine are given in this article The authors find that hypnotism is being used by more and more obstetricians and with good results

Coronet, May, 1957

Liver for Life by Madelyn Carlisle

In this article liver is analyzed for its food value The author states that plain beef, pork, or lamb liver are all equally nutritious

'The Noble Agony of Mario Ponzio, by Geoffrey Bocca

The author tells of pioneering efforts by Professor Ponzio to cure cancer by radiology A heavy schedule of work and repeated exposure to radium burns finally ended the Italian scientist s life at the age of 71

Washington s Cancer Answer by Harold Helfer

People in the District of Columbia area who think they have cancer can pick up the telephone and dial a number that will put them in touch with a physician According to the author of the thousands who call 'Cancer Answer, most have described symptoms which indicated they did not have the disease

What Makes You Tense? by Anne Fromer

This article is based on the work of Dr Hans Selye director of the Institute of Medicine and Surgery at the University of Montreal The author finds that much sickness can be attributed to stress which causes a chemical imbalance which in turn produces specific disease

The Saturday Evening Post, April 27, 1957

How Medical Hypnosis Works, by Milton and Margaret Silverman

The article finds that hypnotism is a highly potent medical weapon It seems to be coming into its own, says the author with surgical and dental applications as well as psychiatric uses

Harper s Magazine, May, 1957

Toads, Mushrooms and Schizophrenia, by Howard Fabing, M D

Today we seem to be standing on the threshold of another series of discoveries of a very different kind which may have equally as far reaching effects on our concepts of the brain's workings and the treatment of mental illness Thus the author leads into an interesting and scholarly history of the relationship between chemistry and mental illness

Indigency Among Doctors

Administration of the Physicians Home [in New York State] for the past twelve years has revealed existing financial conditions among doctors and their widows that neither doctors at large nor the laity realize exist

Organized and incorporated under the charity laws of the State of New York in 1919 to care for indigent doctors, their wives widows, and dependent children, the Physicians Home has functioned continuously and has grown in size scope, and usefulness Its affairs are administered by an executive committee a board of directors of 27, and five trustees Income is *derived from annual [voluntary] membership dues of $10 from* members of the Medical Society of the State of New York, voluntary contributions of $2 00 solicited from State Society members when a bill for dues of the county societies is sent, *contributions from the woman s auxiliaries voluntary contributions* from individuals and bequests

Since our incorporation in 1919 (thirty-seven years) we have had 93 guests Of these 30 were widows three women doctors and 60 were male doctors Our guests have come from many of the 61 counties of the State Applicants are usually in the older age group of sixty to ninety Naturally most are afflicted with partially incapacitating geriatric pathology We simply have never had sufficient funds to accept the cost of nursing home and hospital care When such situations have arisen we have been able to assume only a part of the cost, an amount equal to that which we sent the particular guest each month before his custodial care began

We have never solicited funds outside of the membership of the Medical Society of the State of New York From time *to time we have received bequests (from individuals) which* we have placed in an endowment fund administered by the trustees with the financial advice of the Hanover Bank The income from this fund is used to supplement our other income which is used for the care of guests To my present knowledge similar organizations function only in Massachusetts and Pennsylvania and their budgets are considerably smaller than ours in New York State We have increased our appropriations for these purposes in each succeeding year During our fiscal year October 1 1954 to September 30, 1955, we gave to 34 guests $39 295

The practice of medicine has changed along with the changing times The cost of a medical education has increased Periods of internships residencies, and qualifications for specialty boards certification have likewise lengthened A professional man s income is exaggerated by the laity His expenses are overlooked His financial security in old age is not considered important enough to discuss He is expected to contribute to all charities and keep socially and physically fit Once his earning capacity is established, he is besieged by taxes No matter how necessary they are they are often financially crippling and will always be with him As a doctor advances into his most productive years, for a period of ten to fifteen years his expenses taxes, and family responsibilities increase It is very surprising how savings disappear when one has not anticipated meeting unusual financial responsibilities

When the ages of forties and fifties are reached, parental or collateral family responsibilities may suddenly loom large and financially devastating Preoccupation with professional advancement is a consuming element in a doctor s life, vital as it is, it may well cloud the vision necessary to foresee and establish the future Then comes the period of release from professional appointments, decreased professional activity, and a less *avid interest in advancement—a sort of dulling of the instinct* of competition—the invasion by competing younger doctors, the plateau from which the vista of life is less glamorous, and on looking backward things which might have been seem more poignant The procession, if one survives sufficiently long, leads into further decreased activity and geriatric pathology

Time and again these and similar situations of varying degrees have crossed the desks of those who have processed applications for beneficiary aid from the Physicians Home Tragedy —stark tragedy—tragedy of despair, no domicile or a meager one in an undesirable neighborhood, an empty larder, and clothes too few and tattered to make a respectable appearance, a withdrawal from environment of former associates, a disposal of personal belongings—even furniture, a proud and genteel poverty, a broken spirit, a stone wall, no known means of help or appeal, a state of prayer and bewildering hope—this is the group with whom, as president of the Physicians' Home, I have corresponded and been in contact If their qualifications for beneficiary aid fall within our bylaws, we have accepted them as guests, and instead of shepherding them into a home with segregation and regimentation, we send them a monthly check and allow them to live where and with whom they please This check is sent monthly and continues unless their financial situation betters and they do not need it In the event of death and the inability of the family and friends to finance it, we contribute toward a place of burial and decent funeral, otherwise only a public burial place would be available

Twice we have tried to run an organized home It was very expensive Very few wanted to enter it, and those who did were unhappy and disintegrated rapidly Elderly doctors and their wives and widows seem to prefer to stay in the community in which they have worked all of their professional lives There *they have friends old patients, and the most interests* It is true that even those in large cities desire to terminate their lives there rather than in an unfamiliar and strange countryside A doctor prefers his own library, his chair, his bed, books, and other associations of his home to those of a more formal institution

When our guests become incapacitated from cerebral, visual, auditory, pulmonary cardiac, renal and joint pathology, there is seldom adequate help in their homes to make them comfortable They must be moved into a nursing home This is expensive, and often the care is mediocre Here is where the *Physicians Home is handicapped in helping guests* We simply do not have the funds on hand to pay from $400 to $500 a month for this care The next problem is the difficulty of getting and keeping these doctors or their widows in hospitals Occasionally, a hospital will place one of our guests in a free or endowed bed, but more often the patient is billed by the hospital with very little or no reduction in its rates Again, we cannot help to the extent we would like The next alternative is a city, State, or county institution It is absolutely heart-rending to a family to face this situation The usual attempt to circumvent this practical solution often ends in total financial and social disruption of a family —B C Smith, M D, Indigency Among Doctors, *New York State Journal of Medicine*, Oct 1, 1956

SURGICAL RESECTION FOR PULMONARY TUBERCULOSIS

RESULTS OF STUDY AT AN ARMY THORACIC CENTER

Lieut Col Elmore M Aronstam (MC), U S Army, Robert L Anderson, M D
Phoenixville, Pa, Capt Julio C Davila
and
Lieut Col John B Plum, (MC), U S Army

• *Experience with the surgical treatment of moderately advanced pulmonary tuberculosis in an Army hospital has been summarized for the years 1953 and 1954, when pulmonary resections were done in 93 and 114 patients respectively. The indication for surgery has almost always been the presence of significant residues of necrotic disease, and the majority of the operations have been segmental resections. The opinion formerly held, that overdistention of the remaining lung was harmful, was not borne out by experience. Consequently the number of primary thoracoplasties with lobectomy fell from 11 to 3, and the number of secondary thoracoplasties from 28 to 9. Complications after surgery have become less frequent, but the postoperative morbidity could be reduced even further. Of the 114 patients in the 1954 group, 111 were contacted in 1956. 110 were found to be well, and 75 were known to be gainfully employed.*

The past 10 years have seen two great advances in the treatment of pulmonary tuberculosis: first, the introduction of chemotherapeutic drugs and, secondly, the application of pulmonary resection. Largely as a result of these two factors, we have noted a progressive decrease in mortality from pulmonary tuberculosis; however, incidence figures have been less favorably affected.[1]

With reference to chemotherapy, about 11 years have elapsed since streptomycin was discovered in 1944. Later, aminosalicylic acid and isoniazid were introduced and found to be effective antibiotic agents. The past years have seen intensive investigation with various drug regimens or combinations of these agents. Both pathologically and clinically, they have been found effective. Disappearance of constitutional symptoms, absence of bacteria in sputums, and x-ray regression have been consistently observed. Maximal effect in the average case occurs at about six months. At this time, most shadows of a pneumonic nature have disappeared from the roentgenogram and the shadows of fibrosis, necrotic residuals, or cavities persist. Pathological material from resected specimens confirms the impression that the softer, non-necrotic component of a patient's tuberculosis has largely disappeared at this time in most instances.

Presently, there is no reliable evidence from pathological study that chemotherapy, as it is now employed, has any effect on a caseous or necrotic process once this process has been established. Liquefying and sloughing of a caseous area can continue during chemotherapy.[2] We have not infrequently observed this even after chemotherapy of one year's duration. The similarity of necrotic lesions resected without chemotherapy and resected after chemotherapy is striking.

The factors that result in aging or healing of necrotic and cavitary residual areas are not well understood at present. Tubercle bacilli can be recovered by culture invariably from the necrotic residuals showing only early evidence of healing.[3] In the advanced healing stage, the bacilli can be recovered only with difficulty. The phase of healing of a necrotic lesion is unpredictable from x-ray examination. No correlation has been made between the recovery of tubercle bacilli, the length of chemotherapy, chemotherapeutic regimen, and the degree of cavitary closure of the lesion.[3a] Recoverability of bacilli depends principally on the phase of healing of a necrotic lesion. This is, of course, undeterminable by clinical or radiologic methods. From the foregoing, it is apparent that drug

Another disturbing fact is the appearance of resistance of tubercle bacilli to drugs after prolonged periods of medication The frequency and seriousness of this problem cannot be stated exactly at this time As information accumulates on relapses after chemotherapy and on cultures from resected specimens, this problem may be seen in proper perspective

With reference to resection as an adjunct in the treatment of tuberculosis, a concept of excising localized lung tuberculosis has always been an attractive one In the 1890's, Tuffier, Bloch, and Lawson attempted this In the middle 1930's, inadvertent resection of tuberculous lesions occurred in operative attempts to cure cancer One of the first successful planned resections of lobes for tuberculosis was done by Freidlander in 1935 Dolly and Jones in 1938 further stimulated the use of resection by an encouraging report From this point forward, improved surgical anesthesia, operative technique, and blood replacement greatly assisted in making the rapid advances to the place where today resection has a preferred place in the surgical management of tuberculosis

Many of the first planned resections for pulmonary tuberculosis were done for cavities, particularly in refractory cases As skill improved and chemotherapy became available, cases for resection included those in which there were thoracoplasty failures, totally diseased or destroyed lungs, tuberculous bronchiectasis, lower lobe cavitation, and isolated round lesions In light of pathological and bacteriological evidence available today, it is our feeling that removal of nearly all necrotic and cavitary residuals is desirable Excision has been withheld in our patients because of coexisting infirmities, advanced age, disease distribution of a degree and severity not amenable to surgery, critical pulmonary function, and psychosis Supraperiosteal extrapleural plombage and extrapleural pneumothorax are still used in the bad-risk patient with advanced disease and critical pulmonary function Primary thoracoplasty rarely has been employed Impairment of pulmonary function has, of course, been much greater with thoracoplasty than with resection Tailoring thoracoplasty has been employed concomitantly with resection and after resection, for space problems and persistent leaks The extent to which surgical resection is pursued in treating pulmonary tuberculosis at Valley Forge Army Hospital, an Army center where chest conditions are treated, has varied yearly from use in 15% to use in 20% of all patients admitted for pulmonary tuberculosis

Plan of Treatment

As past clinical experience has indicated that antituberculous drugs exert their maximal clinical and roentgenographic effect at 8 to 10 months of treatment, we have aimed at a total period of chemotherapy preoperatively and postoperatively of nearly one year This has seemed appropriate, as our group of patients have largely moderately advanced disease They do not have advanced, long-standing, bilateral fibrocavitary disease, for which a longer period of therapy and different approach to treatment would be needed

At a point as early in the course of treatment as possible, when the pneumonic component of the tuberculosis has been reversed and necrotic residuals are apparent, surgery is performed This is generally at from four to six months after medication has been started Surgery is followed with completion of chemotherapy and then a short period of leave before the patient goes to duty or discharge Total chemotherapy has been extended beyond the year level in some instances when particularly active areas of disease have been found at the time of surgery

Method of Study

Since 1953, the case histories of all patients undergoing surgery for proved cases of pulmonary tuberculosis have been carefully abstracted Each year a detailed questionnaire is forwarded to the patient When review of the returned questionnaire leaves some doubt as to the patient's health, he is invited back at Army expense for reexamination If this is not practicable, his local physician or the theater surgeon is contacted for further information about the patient Thus, we have a fairly complete follow-up picture on each patient who has undergone surgery

It is apparent at a glance that our patients are, in the majority, young males, although a sizable number of older patients and women have been included Predominantly, our patients were afflicted with moderately advanced pulmonary tuberculosis according to National Tuberculosis Association standards A large proportion of cases were cavitary In every instance, tubercle bacilli were isolated to confirm the diagnosis either preoperatively or from a surgical specimen Preoperative and postoperative drug therapy consisted of combined administration of streptomycin and aminosalicylic acid or isoniazid, streptomycin being given every three days and aminosalicylic acid and isoniazid daily One may see from table 1 that earlier surgery was performed in the 1954 cases than in 1953

Surgical indications have been most exclusively the presence of residual necrotic disease The surgical procedures performed have been, in the majority, segmental resections, although a fair proportion of lobectomies and combined procedures have been done Secondary operations have been performed for complications and space problems Residual fine disease has been left at surgery in about 25% of the cases We do not feel that we can completely resect a patients tuberculous lesions We are interested in removing only the significant necrotic residuals, those that are cavitary or nodular and more than a few millimeters in diameter As far as complications are concerned, 65 of the 93 cases were uncomplicated in 1953 and 94 out of 114 in 1954 All but one patient recovered completely from his operative complication

Pathologically, an average number of smears, stains, and cultures were positive Disease removed was, in the main, moderately active Cavitary residuals were quite frequent Postoperative chemotherapy has varied with each case In general, we have aimed, however, at a minimum of one years drug therapy

Only three unsatisfactory functional results have occurred One patient has a persistent bronchopleural fistula and is still hospitalized In two instances, defective shoulder girdle action secondary to tailoring thoracoplasty was the problem, however, one of these patients is practicing law on a full-time status and one is on full duty in the Army No respiratory embarrassment or insufficiency occurred

The follow-up record for 1953 shows 87 patients (93 5%) have been contacted Of these, 83 are completely well and 62 gainfully employed Of the patients treated in 1954, 111 (or 97 3%) have been contacted One hundred ten are well, and, of these, 75 are gainfully employed Three deaths have occurred in the two years one from the effects of cerebral anoxia occurring during surgery, one from a train wreck, and one death a year after discharge in a patient with far-advanced bilateral disease for whom a thoracoplasty had been performed because of hemorrhage Recurrent exsanguinating hemorrhage occurred as a sudden terminal event one year after discharge

Comment

From a surgical point of view, in the type of patient we have encountered we have preferred to carry out exploration and resection initially, rather than perform a stage of thoracoplasty as the initial procedure In 1953, when a considerable number of tailoring thoracoplasties were performed, we felt that overdistention of remaining lung had a bad effect as far as respiration and recurrence of disease were concerned As there has been no significant recurrence or respiratory crippling, this has not been borne out clinically Since 1954, tailoring thoracoplasty has been performed only for the complications of surgery, such as persistent space, leak, or fistula This procedure has consisted of stripping the undersurface of the first rib, doing a modified apicolysis, and removing segments of ribs 2, 3, and 4 The transverse processes are preserved

We have been extremely reluctant to perform concomitant resection and thoracoplasty, as postoperative complications have been significant (11 complications in 13 cases in 1953 and 6 complications in 4 cases in 1954), furthermore, the postoperative courses have been more stormy because of paradoxical respiration and difficulty in raising secretions postoperatively

Particularly gratifying has been the increase in the number of uncomplicated cases over the two years (65 out of 93 in 1953 and 94 out of 114 in 1954) During this period, our staff was considerably reduced, indicating that an enthusiastic, qualified staff with excellent ancillary support in medicine, anesthesia, nursing, and physiotherapy can reduce complications

Persistent air leaks and space problems have occurred principally following segmental resection Seventy-five per cent of fistulas occurred after lobectomy All fistulas, leaks, and space problems were successfully treated, with one exception All other postoperative problems have been effectively corrected or overcome

It is apparent from this point of vantage that recurrence after resection has not been a problem Surgery in well-equipped centers is safe but still hampered by postoperative morbidity This has not been insurmountable, however It is obvious that patients can and do uniformly return to full activity when this plan of treatment is followed The comparison of these results with a follow-up study of similar patients treated solely with medical regimens will be most informative as data become available

SURGICAL TREATMENT OF COARCTATION OF AORTA

REPORT OF THE SECTION ON CARDIOVASCULAR SURGERY, AMERICAN COLLEGE OF CHEST PHYSICIANS

William R. Rumel, M.D., Salt Lake City, Charles P. Bailey, M.D., Philadelphia
Paul C. Samson, M.D., Oakland, Calif., David H. Waterman, M.D., Knoxville, Tenn.
and
Richard J. Bing, M.D., Birmingham, Ala.

• *The life expectancy at birth of a patient with coarctation of the aorta is estimated at 32 years or less. Surgical correction requires the use of relatively uncommon and potentially hazardous techniques. Opinion is divided regarding the advantages of aortic homografts as compared with woven tubes of plastic fabric in bridging the defects left by resection of long coarcted segments. There were 138 operative deaths among 1,601 patients treated surgically. The most important cause of death was cardiovascular failure, second and third in order of importance were disruption of the anastomosis and hemorrhage. Mortalities were lower in the age group from 4 to 15 years than in the younger and older age groups. The over-all results were considered satisfactory in 96.3% of 1,405 patients from whom accurate data were obtained three months after operation.*

When a patient and his physician are faced with the problem of deciding whether to use a major therapeutic measure—surgical or medical—the decision is relatively simple if the following questions can be answered with reasonable accuracy. 1. What is the outlook without therapy? 2. What is the morbidity and mortality associated with the therapeutic procedure? 3. What are ultimate results following the measure under consideration?

With reference to the surgical treatment of coarctation of the aorta, the first question can be answered adequately, but the answers to the second and third have not been settled to date in the medical literature because of limited experience from the standpoint of time as well as from that of the total number of cases reported. The primary purpose of this report is to attempt to answer these questions beyond reasonable doubt, and the secondary purpose is to bring forth any information that may be helpful in improving the results obtainable. The report is based upon the latest possible follow-up study of 1,601 cases treated surgically by 36 of the 55 members of the surgical advisory committee to the subcommittee on cardiovascular surgery of the American College of Chest Physicians. The members of this committee are prominent cardiovascular surgeons practicing in representative areas throughout the world.

The Outlook Without Surgical Correction

The question of outlook for the patient with coarctation of the aorta not corrected surgically can be answered with reasonable accuracy. The average duration of life in 200 cases studied in 1928 by Abbott[1] was 32 years, and in an additional group of 104 cases reported subsequently in 1947 by Reifenstein and co-workers[2] it was found to be 30.5 years. As judged by Brown,[3] only one-tenth of patients live past the age of 50. In view of this rather dismal outlook, the need for a satisfactory method of treatment is obvious.

Mortality and Morbidity Associated with Surgical Correction

In 1945, Crafoord and Nylin[4] and Gross and Hufnagel[5] independently reported the feasibility of surgical correction of coarctation of the aorta. Although a fairly large number of cases has been reported in the medical literature since that time, a simple unqualified answer to the question regarding operative mortality and morbidity cannot be given. In dealing with an individual patient, we must consider such variable factors as age, the presence of associated correctable and/or uncorrectable defects, irreversible cardiovascular, renal, or central nervous system complications, and type of coarctation, as well as such factors as the experience of the operating team and the technique used. The information to follow should clarify considerably some of these uncertainties.

The over-all operative mortality rate, up to three months after surgery, in the 1,601 collected cases was 8.6%. It was most favorable, 6.8%, between the ages of 4 to 15 years. As one might expect, higher rates were present in the young and in the old. In the infant-to-3-year age group, the operative mortality rate was 16.2%, and in the group over 30, it was 11.3% (table 1).

TABLE 1.—*Operative Mortality Rates According to Age in 1,601 Collected Cases*

Age, Yr.	Cases, No.	Deaths No.	Deaths %
Infant-3	130	21	16.2
4-15	616	42	6.8
16-30	653	52	7.9
Over 30	202	23	11.3
Total	1,601	138	8.6

However, it must be appreciated that in the less favorable groups there was a higher incidence of uncorrectable associated defects and/or serious irreversible complicating conditions such as heart failure, renal impairment, and aneurysms. Operation before these conditions become irreversible, regardless of the age of the patient, should bring about a significant reduction in the mortality rates as well as improvement in results.

The causes of death with their incidence are given in table 2. By combining heart failure, pulmonary edema, shock, and cardiac arrest or ventricular fibril-

---

Read before the Section on Diseases of the Chest at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

lation—all of which are related—it is apparent that 37.7% of the 135 operative, postoperative, and late deaths were due to these cardiovascular conditions.

Disruption of the anastomosis accounted for 22.4% of the operative and postoperative deaths. In 11 of the 28 cases, proved or probable infection was present at the operative site. In four additional cases postoperative subacute bacterial endarteritis developed; this may well have been an important factor, although the relationship was not specified in the answers to the questionnaires. Measures to minimize airborne contamination resulting from the long time of exposure of the wound, along with more intensive prophylactic postoperative antibiotic therapy, should serve to lessen this serious problem.

TABLE 2.—*Causes of Death and Their Incidence in 1,536 Cases of Coarctation of the Aorta*

	Operative and Postoperative	Late	Total
Heart failure, pulmonary edema, shock	30	3	33
Disruption of anastomosis	28	0	28

Necrosis and thrombosis of anastomosis	1	0	1
Gastroenteritis	1	0	1
Drowning	0	1	1
Suicide	0	1	1
Unspecified	6	2	8
Total	125	10	135

Hemorrhage during surgery, usually from thin-walled, dilated intercostal arteries, was responsible for 12.8% of deaths in the operative and postoperative period. As the experience of operating surgeons increases, deaths from this technical cause as well as from disruption should decrease, particularly if this relatively uncommon and potentially hazardous procedure is not performed by an unnecessarily large number of surgeons.

A consideration of the remaining causes of death points out clearly that a significant number either were unrelated to the surgical procedure or were in part avoidable. Even without being optimistic about future improvement in mortality rates, the results to date seem to justify earlier and more widespread application of surgical treatment.

Remote Results Following Surgical Correction

Inasmuch as our experience dates back only to 1945, the question of the ultimate results following surgical correction of coarctation of the aorta can be answered only partially; however, the trends to date can be of definite help in advising our patients properly. With reference to the over-all clinical result obtained following surgery, accurate figures were supplied on 1,405 patients surviving the three-month postoperative period. The result was satisfactory in 96.3%. The effect on blood pressure was given specifically in 1,230 survivors (table 3).

Satisfactory relief of hypertension followed surgery in a total of 1,171, or 95.2%, of patients. Entirely normal readings were present in 72%, and in only 4.8% of patients did serious hypertension persist. The incidence of persistent hypertension increased progressively as the patient's age increased. Fifteen of the reporting medical advisors recommend the use of aortic homografts to bridge the defects left by resection of long coarcted segments, 11 prefer woven tubes of plastic fabric. The remainder were uncertain.

Conclusions

A study of 1,601 cases of coarctation of the aorta treated surgically by 36 members of the surgical advisory committee of the American College of Chest Physicians indicates that the over-all operative mortality rate was 8.6%. A satisfactory clinical result was obtained in 96.3% of the survivors. The most frequent causes of death and their respective incidences were as follows: (1) various cardiovascular complications, 37.7%, (2) disruption of the anastomosis, 20.7%, and (3) hemorrhage at the time of surgery, 11.8%.

The results obtained to date are good enough to justify general application of the surgical treatment of coarctation of the aorta. In the future, better results undoubtedly will be obtained by (1) operation before patients enter the advanced age group, (2) operation earlier in infants and young children, (3) more adequate management of serious associated defects, and (4) improvement, as a result of further experience, of management of the technical problems peculiar to the condition.

ILEOCOLITIS

Harry Yarnis, M D, Richard H Marshak, M D
and
Burrill B Crohn, M D, New York

• *Regional ileitis may be associated with ulcerative or granulomatous colitis, the diagnosis depending upon the amount of fibrosis and scarring as well as the presence of giant cell systems and epithelioid cells Ileocolitis is a term used to indicate the presence of the combined forms, whose presenting symptoms are fever, cramps, and diarrhea Medical treatment should be attempted in all cases, unless there are definite indications for surgical therapy such as recurrent massive hemorrhage, recurrent bouts of intestinal obstruction, or persistent fistulas*

Ileocolitis is a term that has been loosely used to describe both specific and nonspecific forms of inflammatory disease involving the terminal ileum and proximal part of the colon Before 1930 practically all of these cases were considered as hyperplastic ileocecal tuberculosis because segmental colitis and regional ileitis were not known

Nonspecific ulcerative colitis was long recognized in its universal and distal forms since its original description in 1875 by Wilks and Moxon,[1] who named the disease after the gross appearance of the colonic mucosa It was not until 1930 that Bargen and Weber[2] described "regional migratory chronic ulcerative colitis,' a segmental type of colitis, which began in the proximal part of the colon and spread distally, usually sparing the lower sigmoid and rectum In both the universal and segmental types of colitis the terminal ileum is frequently involved by retrograde extension due to regurgitation of the infected colonic contents through an incompetent ileocecal valve This "backwash' ileitis is found in 24% of cases in universal ulcerative colitis, but the incidence is much higher in the segmental type, having been reported in 40% of 77 cases by Crohn, Garlock, and Yarnis[3] in 1947 It is important to note that the pathological process in backwash' ileitis is ulcerative and exudative in nature and confined to the mucosa and submucosa There is no evidence of the sclerosing granulomatous process characteristic of regional ileitis

Terminal ileitis was originally described in 1932 as a granulomatous disease limited distally by the ileocecal valve without involvement of the cecum or proximal part of the colon However, only two years later Colp[4] published a report of a case in which he resected a nonspecific granuloma of the terminal ileum and cecum Subsequently numerous case reports were published of extension of regional ileitis into the proximal part of the colon The highest incidence of colonic involvement in regional ileitis was reported in 1951 by Rappaport, Burgoyne, and Smetana,[5] who published a report of 100 cases of regional ileitis, with extension into the colon in 55 instances However, in many of these cases the granulomatous extension into the colon was minimal and could be detected only by microscopic technique In our experience granulomatous involvement of the colon in regional ileitis has not been common

The granulomatous nature of regional ileitis and the exudative inflammatory process of the typical case of ulcerative colitis is well recognized and undisputed However, there is much disagreement concerning the pathology of segmental colitis On the one extreme Warren and Sommers[6] regard these two diseases as morphologically different and deny the existence of granulomatous colitis On the other hand, Neuman and Dockerty[7] reported 25 resected specimens of segmental colitis in which there was a nonspecific granulomatous process producing a thickening of the entire colonic wall Wells[8] also published a report of cases of segmental colitis that he considered to be a colonic type of granulomatous ileitis and described the typical microscopic appearance of a granuloma with giant cells and epithelioid tubercle formation in the colon

From the Medical Service and the Department of Radiology of the Mount Sinai Hospital

Read before the Section on Gastroenterology and Proctology at the 105th Annual Meeting of the American Medical Association Chicago, June 12, 1956

Brooke and Cooke[9] recently described a form of ileocolitis due to dysfunction of the small intestine, causing poor fat absorption and steatorrhea This produces superficial ulcerations in the ileum that gradually spread through the ileocecal valve to involve the colon It is important to recognize this type of case, because surgical intervention is invariably followed by diffuse recurrence due to the progressive nature of the disease

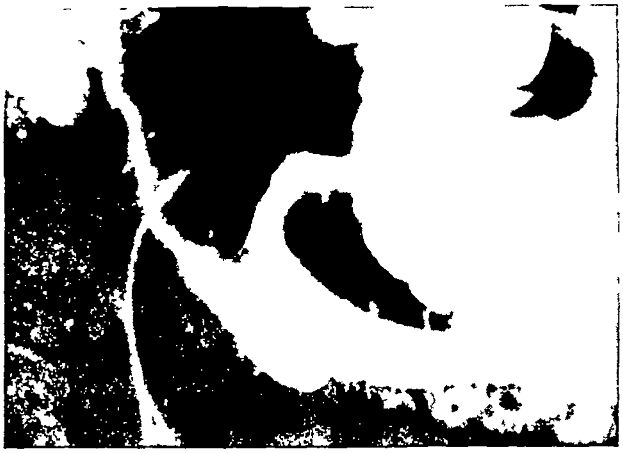

Fig 1 —Typical terminal ileitis with sinus tracts and fistulas

At the Mount Sinai Hospital in New York the pathologists have almost universally reported resected specimens of segmental colitis as ulcerative in nature Occasionally reports of cicatricial or hyperplastic colitis are encountered There have been only rare instances where regional ileitis was reported to extend into the colon It appears that the diagnosis of an ulcerative or granulomatous process depends upon the amount of fibrosis and scarring as well as the presence of giant cell systems and epithelioid cells Grossly the presence of skip areas in the colon and thickening of the colonic wall favor the diagnosis of granulomatous colitis In reviewing many of the specimens reported as ulcerative colitis, focal areas containing giant cells and epithelioid tubercles were found, so that both granulomatous and exudative inflammatory processes must be present in the same colon It is therefore apparent that in a small number of these combined cases the pathological process is occasionally granulomatous rather than ulcerative in nature Whether this deviation in pathology has any significance is problematical, but it is in this group of cases that the interpretation of the type of inflammatory process by individual pathologists has differed and caused confusion Certainly the clinical course is no different in one type than in the other

It therefore appears that regional ileitis may be associated with ulcerative colitis or "granulomatous" colitis In this paper we will use the term 'combined ileocolitis to signify the presence of granulomatous ileitis and ulcerative colitis When granulomatous ileitis is combined with granulomatous colitis the term "granulomatous ileocolitis" will be used Furthermore, the combinations of these two diseases may take place simultaneously (synchronous) or may occur in sequence (metachronous) Thus, if ileitis is designated as 'E and ulcerative colitis as C,' and granulomatous colitis as "G," the following variations may occur E, pure regional ileitis, C, pure ulcerative colitis, G, pure granulomatous colitis, EC, synchronous combined ileo colitis, EG, synchronous granulomatous ileocolitis, E plus C, primary ileitis to which later ulcerative colitis is added, and C plus E, ulcerative colitis that is later complicated by ileitis

The 60 cases of ileocolitis used in this paper are taken from our private office files and have been collected over a 26-year period, there are 58 cases of combined ileocolitis and only 2 cases that were reported as granulomatous ileocolitis However, five cases were included in the combined ileocolitis group because our pathologist reported the colonic involvement as ulcerative colitis, despite the presence of marked fibrosis and thickening of the wall It would appear that by many pathologists these colonic lesions would have been considered more consistent with the diagnosis of granulomatous colitis In 40 cases both ileitis and ulcerative colitis were present at the onset of the disease and the combined ileocolitis was therefore "synchronous" in origin In 18 cases either ulcerative colitis or ileitis was originally present but, after an attempt to cure the original disease by surgical intervention, the second disease developed This group of cases of combined ileocolitis may be called "metachronous" in nature, signifying that the combined diseases succeeded or followed each other There were two cases of granulomatous ileocolitis, one with extensive involvement of the colon including the rectum and the second with a granulomatous process localized to the ascending colon

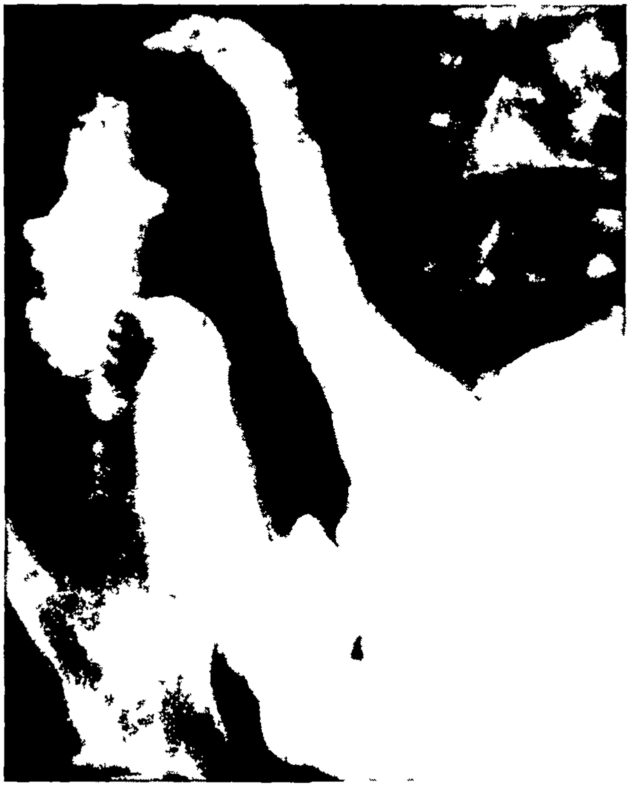

Fig 2 —Right-sided ulcerative colitis with involvement of terminal ileum (backwash ileitis)

Although ulcerative colitis and regional enteritis have different pathological pictures, they appear to be related diseases clinically, causing somewhat similar symptoms and occurring more frequently in the younger age groups There were 27 females and 33 males in our series of cases The most frequent onset occurred in the second and third decades, with the clinical course in two cases beginning at the age of 9 years However in one case a man was 70 years of age at onset

The anatomic distribution of the involved segments in ileocolitis may be so variable and heterogenous as to make an exact classification impossible For practical purposes the 42 cases of synchronous ileocolitis are divided into the following groups terminal ileum and ascending colon, 18 cases, terminal ileum and transverse colon 2, terminal ileum and distal part of colon, 5 terminal ileum and entire colon, including rectum 1, ileum, jejunum, and entire colon to sigmoid, 5, and terminal ileum and entire colon to sigmoid, 11 The 18 cases of metachronous ileocolitis are divided into two groups In 13 instances the primary disease was in the terminal ileum and, after an ileotransverse colostomy was performed for the cure of the original disease, ulcerative colitis developed In five cases the primary disease was ulcerative colitis involving the entire proximal part of the colon, excepting the rectum and sigmoid, in four of these cases granulomatous ileitis developed after subtotal colectomy and ileosigmoidostomy had been performed In one case an ileostomy was required after the original ileosigmoidostomy had been carried out After this the patient developed a granulomatous jejunitis and five years later a granulomatous ileitis

Fig 3 —Regional enteritis with granulomatous colitis to the hepatic flexure (granulomatous ileocolitis)

Roentgenographic

In each of the cases described above, regional enteritis was present, associated with an inflammatory lesion in the colon The characteristic findings of regional enteritis were unaffected by the inflammatory disease in the colon, whether ulcerative or granulomatous and presented the alterations described in various articles [10] consisting of narrowing of the intestinal lumen, rigidity, ulceration of the mucosa, inflammatory polyps, skip areas, fistulas, and separation of the involved intestinal loops due to thickening of the intervening mesentery and enlarged lymph nodes (fig 1) Marked stenosis of the distal part of the ileum associated with proximal dilatation was present in 16 cases In the majority of cases, the inflammatory process was confined to the distal part of the ileum In five cases a diffuse jejunoileitis was present In most cases the exact extent of the involvement of the ileum could be stated fairly accurately, however, in several cases numerous fistulas and sinus tracts resulted in matting together of the loops of intestine, and it was difficult to state, with any degree of accuracy, the exact extent of involvement It is important to differentiate regional ileitis from so-called backwash ileitis, which may be associated with diffuse ulcerative colitis or segmental colitis (right-sided ulcerative colitis) In backwash ileitis (fig 2) the narrowing of the intestinal lumen was not as marked as when there was granulomatous involvement The mucosa usually presented minimal ulceration, fistula formation was rare, skip areas were not seen, and marked separation of the intestinal loops was not

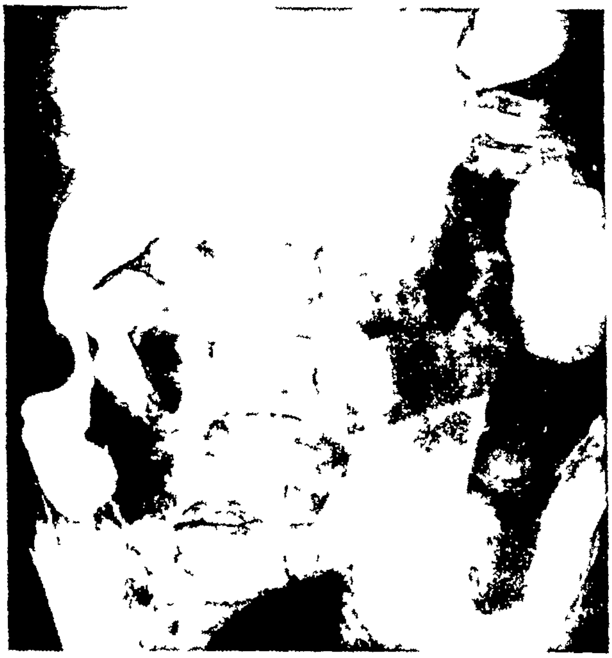

Fig 4 —Right sided ulcerative colitis with regional enteritis

usually observed In some of these cases, however, the ulceration of the mucosa was marked and considerable spasm with a "string sign,' such as has been noted in regional ileitis, was observed This finding was unusual, and the degree of narrowing and rigidity usually seen with regional enteritis associated with proximal dilatation was absent

Although the granulomatous nature of the lesion in the ileum could be identified fairly accurately, it was difficult to determine radiologically whether the alterations in the colon were ulcerative or granulomatous in nature In cases where there was an associated granulomatous colitis the findings in the colon were usually limited to a short segment that extended approximately to the hepatic flexure and strikingly resembled the lesion in the ileum, in that there was marked narrowing and rigidity (fig 3) Skip areas in the colon were occasionally observed Fistula formation and marked ulceration were uncommon in granulomatous colitis

When the lesion in the colon was diffuse, extending to the splenic flexure and mid-descending colon, the process was usually due to and resembled ulcerative colitis, in that there was slight to moderate rigidity and absent or distorted haustral marking (fig 4) Ulceration of the mucosa was more frequent with and without inflammatory polyps Shortening of the colon is a more common feature in ulcerative rather than granulomatous colitis Stricture formation can occur in both ulcerative and granulomatous disease In many instances, it was impossible to state the exact extent of the inflammatory process in the colon, and specific roentgenographic findings to differentiate ulcerative colitis from granulomatous colitis were not available It would appear reasonable to assume, in the cases in which typical regional ileitis is associated with involvement of a short segment of colon in continuity, that the colitis is granulomatous in nature, especially since the lesions in the colon have such a striking resemblance to the lesions in the ileum However, in the one case where there was a typical terminal ileitis associated with a diffuse granulomatous colitis, the x-ray appearance in the colon could not be differentiated from ulcerative colitis

In the colon, the exact termination of the disease could not always be determined At operation and pathologically, ulceration was present that was not seen radiologically Not infrequently on the roentgenograms, the lesions appeared sharply demarcated, however, pathological examination revealed further distal ulceration though to a minimal degree

Clinical Aspects

Fever, cramps, and diarrhea are the presenting symptoms of ileocolitis The fever is present during the active phases of the disease, with temperatures frequently ranging from 101 to 103 F (38 3 to 39 5 C), but in the acute cases with high toxicity they may reach as high as 106 F (41 1 C) Leukocytosis with polynucleosis corresponds to the fever, with leukocyte counts ranging from 12,000 to 16,000 per cubic millimeter and occasionally reaching 20,000 However, counts below 10,000 per cubic millimeter with a high polynucleosis and many young unsegmented polymorphs with toxic granulations are frequently found in the acute cases The sedimentation rate corresponds to the fever and leukocytosis but usually remains elevated during the afebrile periods until the inflammation completely subsides Foul diarrhea with or without bloody stools and cramps is usually present, but the tenesmus and rectal urgency found in universal ulcerative colitis are absent In four cases there was an absence of diarrhea and even constipation was noted Gross hemorrhage was present in nine instances and was massive, producing shock, in three cases Melena was noted in two cases

Anorexia and weight loss are progressive during the recurrences, and in extreme cases losses of more than 50 lb (23 kg) may occur, producing cachexia and malnutrition Glossitis, rhagades, and other signs of vitamin B deficiency are frequent Deficiency of vitamin K, causing prolonged prothrombin time, is found in the more severe cases Secondary anemia is consistently present, with hemoglobin levels ranging between 9 and 10 Gm per 100 cc Hypoproteinemia may be mild, with blood protein values up to 6 Gm per 100 cc, but in the more extensive cases the protein values may drop to 4 Gm, with a marked decrease in the serum albumin Nutritional edema was only occasionally observed Hypocalcemia and tetany were observed in only two cases Arthritis was present in 16 instances and usually involved the large joints An associated duodenal ulcer was present in five patients

An abdominal mass was palpable, usually in the right lower quadrant, in 24 cases Splenomegaly was noted in three instances, and clubbing of the fingers was present in four cases Erythema nodosum occurred five times in the lower extremities, and stomatitis with ulcerative pharyngitis twice Phlyctenular conjunctivitis was noted once Intestinal obstruction causing abdominal distention and fluid levels in the small intestine occurs rarely and usually subsides after intestinal intubation

Internal fistulas originating in the diseased terminal ileum and extending to the cecum and other parts of the colon, existed in eight cases, and in one instance a jejunoileal fistula occurred External fecal fistulas, opening on the anterior abdominal wall, complicated seven cases Four of these fecal fistulas were secondary to a perforated ulcerative colitis of the sigmoid, and two fistulas originated in the terminal ileum Rectal complications were frequent Perirectal abscesses and fistulas were present in 23 cases, 4 cases were associated with rectovaginal fistulas, and in one male there was a deep rectourethral fistulous tract

Medical Therapy

Medical treatment should be attempted in all cases of ileocolitis unless there are definite indications for surgical therapy, which will be discussed subsequently The essential part of the therapy in acute stages consists of supportive therapy, including bed rest, bland low-residue diet, fluids given intravenously, and plasma or blood administered whenever necessary Injections of crude liver extract and vitamins are also essential The insoluble sulfonamides and antibiotics such as tetracycline, dihydrostreptomycin, and neomycin are used to combat secondary infection Penicillin is of no value for the treatment of this disease and its complications However, steroid therapy has been of definite value and is especially effective in the acute stages of high fever and intoxication This is best administered in the form of corticotropin (Acthar) gel parenterally or in the newer long-acting zinc corticotropin preparations that need to be administered only once in 48 to 72 hours Once the desired improvement is obtained, the steroid therapy may then be continued with prednisone (Meticorten) or hydrocortisone (Hydrocorten) orally In many instances results of the oral use of steroids are disappointing because of their poor absorption One patient with diffuse disease of the small and large intestine made a remarkable recovery, gaining 30 lb (14 kg), and was able to resume his work as a mail carrier after treatment with corticotropin gel However he must continue a maintenance dose of 10 units of corticotropin gel daily to prevent the recurrence of his symptoms Another patient, 70 years of age, with high temperature, marked intoxication, and erythema nodosum of the legs became asymptomatic after six injections of corticotropin

Of the 18 patients treated medically, one is cured, 2 are well, 5 are improved, and 8 continue to have frequent recurrences and are in a chronic state of malnutrition One patient died at the age of 70, and one patient was lost to follow-up The patient who was cured had a typical terminal ileitis with concurrent involvement of the transverse colon He was treated with nonspecific protein shock therapy with use of typhoid vaccine given intravenously He made a dramatic response, and four years later x-rays revealed a normal mucous membrane throughout the entire colon and a slight distortion of the terminal ileum Now, 18 years after the original illness, the man is well

Surgical Management

In this series 42 patients were treated surgically, with multiple operations being required in most instances The surgical approach to the treatment of ileocolitis presents numerous and complex problems even to the most experienced surgeon In general surgical intervention is most successful where the disease is localized to the distal part of the ileum and proximal part of the colon and the patient has not responded to medical therapy Local palliative resections of stenotic diseased areas of ileitis and jejunitis are frequently necessary when intestinal obstruction exists Occasionally massive resections of the colon and small intestine have been necessary because of exsanguinating hemorrhage or progressive disease

Synchronous Ileocolitis —There were 24 cases of synchronous ileocolitis In 12 of these cases the disease was limited to the terminal ileum and ascending colon Ileocolic resection was performed in nine and a short-circuiting procedure (ileotransverse colectomy) in the other three instances Results were good in five cases and poor in six due to recurrent disease, and one patient died after a secondary resection

In the remaining 12 cases, one patient had an ileosigmoidostomy with transection of the ileum for terminal ileitis and transverse colitis, he is well and weighs 190 lb (86 kg) In two cases of terminal ileitis and proctitis an ileotransverse colostomy was performed, followed by progression of the colitis with perianal abscesses finally necessitating ileostomy In six cases, ileocolic resection and ileosigmoidostomy were performed for terminal ileitis and right-sided colitis Four of these patients required ileostomy after the rectum became involved One patient is improved, one is in poor condition due to recurrent disease

One case of terminal ileitis was associated with a granulomatous colitis involving the entire colon, including the rectum Exactly one year prior to the time of writing, a total colectomy and resection of the terminal ileum was performed at one stage, and the pathological specimen revealed typical granulomatous ileitis associated with a thickened colon containing giant cell systems and epithelioid tubercles, suggesting the diagnosis of granulomatous colitis, the patient made an uneventful recovery and gained 40 lb (18 kg)

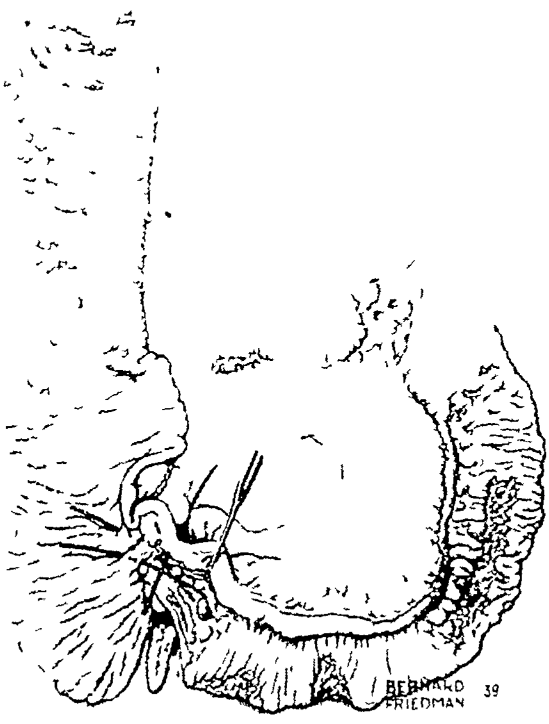

Fig 5 —Terminal ileitis with fistulas and skip areas Regional colitis with pseudopolyps

In two cases there was a diffuse ileojejunitis associated with an ulcerative colitis involving the entire colon excepting the rectum In one patient an ileosigmoidostomy and subtotal colectomy were performed However, he continues in poor nutrition with acute exacerbations of fever and diarrhea due to the residual ileojejunitis The second patient has been observed for 18 years and presents the life history of ileojejunitis and right-sided colitis with the gradual progression of the disease to involve the entire colon In this patient the clinical course began with a terminal ileitis and proximal colitis at the age of 20 years subsequently he developed a diffuse ileojejunitis with a gradual extension of the colitis to involve the entire colon, including the rectum Over the course of 16 years, multiple resections of the small and large intestine were performed, and at present he is left with an ileostomy situated 7 ft from the ligament of Treitz His serum electrolytes and hemoglobin are stabilized at normal levels His weight is constant, and he is restored to working efficiency A typical granulomatous ileitis was reported by pathological examination of the specimen, the ascending colon revealed a chronic 'hyperplastic and polypoid colitis (fig 5) The remaining parts of the transverse and descending colon including the rectum revealed a typical chronic ulcerative colitis

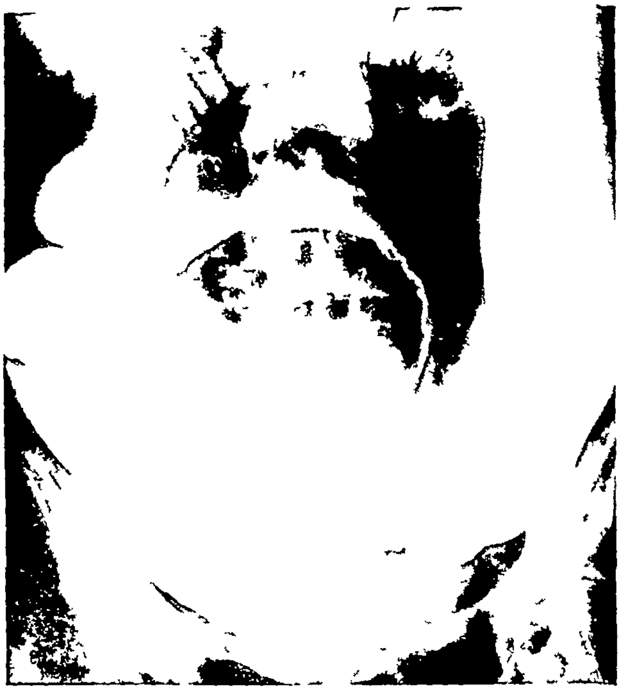

Fig 6 —Ileosigmoidostomy with recurrent granulomatous ileitis after resection for right-sided ulcerative colitis (metachronous ileocolitis)

Metachronous Ileocolitis—There were 18 cases of metachronous ileocolitis Thirteen of these began initially with terminal ileitis, and ulcerative colitis developed after an ileotransverse colostomy with or without ileocolic resection had been performed In one case the secondary colitis was restricted to the transverse colon and after a subsequent resection the patient was well A second patient after a short-circuiting procedure for terminal ileitis developed diffuse ulcerative colitis but his disease has been in a continuous remission for the past three years In two other patients who had an ileocolic resection for ileitis, results are fair due to a mild but persistent ulcerative colitis In one case death followed infection with clostridia, one patient was lost to follow-up The remaining seven patients who originally had terminal ileitis developed a subsequent ulcerative colitis after surgical intervention for the cure of the ileitis In all eight patients the subsequent ulcerative colitis has been severe, requiring ileostomy in three instances One of the latter cases began with a terminal ileitis when the patient was 28 years of age After an ileotransverse colostomy and subsequent ileocolic resection including 4 ft of diseased terminal ileum, there was marked improvement for seven years He then developed increased diarrhea associated with chills and fever, barium enema three years ago revealed ulcerative colitis involving the sigmoid and lower part of the descending colon Despite intensive treatment, including steroid therapy, his course was downhill, and resection of the entire distal part of the colon, including the rectum, was required for severe advanced ulcerative colitis causing massive hemorrhage At present the ileostomy drainage averages 3 liters, but the patient's weight is stabilized at 130 lb (59 kg) and his blood electrolytes are within normal range without intravenously given supplements

The other five cases of metachronous ileocolitis began with right-sided ulcerative colitis for which ileosigmoidostomy and subtotal colectomy were performed The resected terminal ileum in two of these cases was normal and in the other three cases presented the typical "backwash' ileitis Within five years a true granulomatous ileitis developed in four of these patients in the new termial ileum proximal to the site of the ileosigmoidostomy Of these four patients, two required subsequent ileostomy due to rectal complications and are well now The third patient developed mild proctitis and duodenal ulcer The fourth

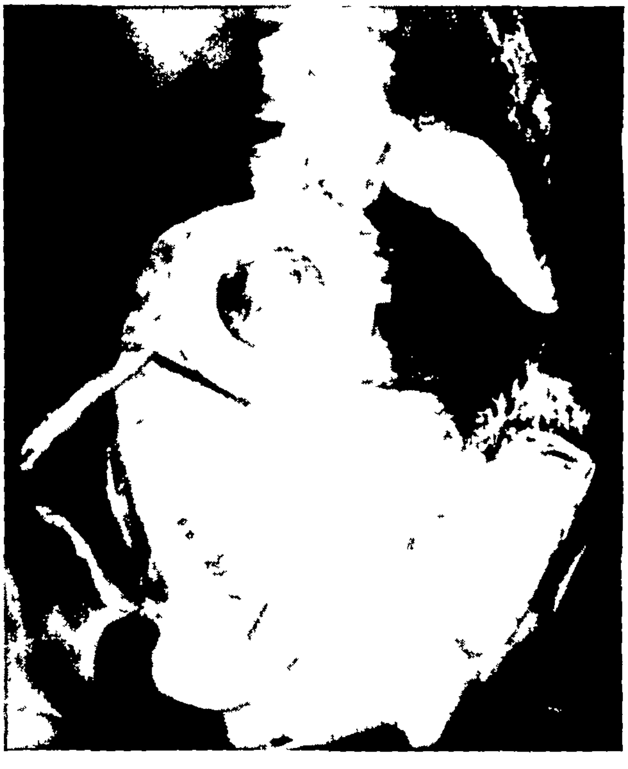

Fig 7 —Granulomatous ileitis with skip area proximal to ileostomy

case is significant because granulomatous ileitis recurred twice after resection for right-sided ulcerative colitis and yet the sigmoid and rectum are still perfectly normal This patient is now 28 years of age, at the age of 18 she underwent a subtotal colectomy and ileosigmoidostomy for right-sided ulcerative colitis with a fecal fistula to the abdominal wall Five years later she developed recurrent symptoms and radiographic studies (fig 6) revealed a typical granulomatous ileitis proximal to the ileosigmoidostomy, 46 cm of terminal ileum was resected and granulomatous ileitis with fistula formation was revealed She had a normal full-term pregnancy three years ago, however, during the eighth month of her second pregnancy she had a recurrence of fever and diarrhea, and at the time of cesarean section 16 months ago acute ileitis was seen proximal to the site of the anastomosis Because of recurrent intestinal obstruction, 18 in of granulomatous ileitis was resected three months ago The patient now weighs 115 lb (52 kg), has only three to four stools a day, and is an active housewife despite the presence of a high ileosigmoidostomy

The fifth patient, with a subtotal colectomy and ileosigmoidostomy for right-sided ulcerative colitis, developed proctitis requiring ileostomy At this time a segment of granulomatous jejunum 18 in in extent was resected Six years later she developed granulomatous ileitis involving the terminal 24 in of ileum immediately proximal to the site of the ileostomy (fig 7) Both the jejunitis and the ileitis were typically granulomatous, containing skip areas, and did not resemble the superficial ulcerative ileitis frequently seen after ileostomy This ulcerative ileitis is prone to occur when there is stenosis of the ileostomy stoma causing obstruction We have seen this complication five times In addition we have had two patients in whom ileostomy was performed who developed a severe necrotizing diffuse ileojejunitis with a fulminating course complicated by massive hemorrhage and having a fatal outcome within 48 hours

Prognosis and Results

Of the 18 patients treated medically, 3 are well and 5 are improved, but 8 are in poor condition, with frequent recurrences One patient died and one patient was lost to follow-up Results in the 42 surgical cases can be considered good in only 10 patients, 7 are improved, 20 are poor, 2 died, and 3 patients are lost to follow-up In 13 of the surgical cases, patients eventually required ileostomy As expected, the prognosis in the combination of these two severe inflammatory diseases is poor When the disease remains localized to the terminal ileum and small segments of the colon, the results are generally good Many of these patients in our series had complicated cases and had been referred to our office after previous unsuccessful attempts at medical or surgical cure

After 25 years of experience in handling these complicated cases of combined ileocolitis, one learns the value of a conservative medical approach Expectant therapy should be the treatment of choice unless there are urgent surgical indications such as recurrent massive hemorrhage, recurrent bouts of intestinal obstruction, or persistent fistulas We have found steroid therapy, especially in the form of corticotropin injection, of definite value in causing remissions and maintaining sustained improvement The best surgical results in our series were obtained when the patients had been observed for a long period of time and the disease remained localized to the distal part of the ileum and proximal part of the colon Recurrences have followed invariably when the patient was operated on during the diffuse stages and the surgeon was unable to delimit the segments of involved disease In the presence of diffuse disease, multiple resections of localized segments causing active symptoms will often bring about marked remission and slowly enable the remainder of the intestine to take over the absorptive function However, in some instances massive resections of the small and large intestine may be necessary, these are now possible with satisfactory results after preoperative preparation with multiple transfusions and antibiotics

In these confusing, complicated, often bewildering forms of combined disease (ileitis and colitis or ileocolitis), no absolute rule can be laid down for the approach to surgical therapy Every case must be considered on an individual basis, since there are so many various and so many possible combinations of the different factors Where medical therapy fails, where fistula formations, abdominal masses, perirectal abscesses, and fistulas persist, where gross massive hemorrhage or small obstruction of the small intestine supervenes, one has no choice but to ask for radical surgical interference And this in face of the fact that radical surgical intervention seems to offer little but amelioration and is so often followed by disappointing recurrences or by spread of the disease to new anatomic territories Medical cures or permanent cures under conservative therapy are very few

CHANGES IN CIRCULATION CONSEQUENT TO MANIPULATION DURING ABDOMINAL SURGERY

Angelo G Rocco, M D
and
Leroy D Vandam, M D, Boston

• *The cardiovascular responses to manipulation of the abdominal viscera were studied in 68 patients undergoing laparotomy The anesthesia most frequently used was nitrous oxide in combination with ether and other agents, and continuous recordings were made of the pressure in the brachial artery, the electrocardiogram, electroencephalogram, and intrathoracic pressure The common response, obtained in 55 patients, was arterial hypotension with or without bradycardia No one area or maneuver could be depended on to elicit this response It was not explained by purely mechanical factors such as occlusion of veins It appeared to be a reflex response to the stimulation of localized receptors, which must be assumed to be more frequent in the upper part of the abdomen and on the parietal, rather than the visceral, peritoneum*

During anesthesia for abdominal surgery, changes in blood pressure and respiration are frequently detected as exploration of the abdomen is performed The existence of such reactions has been known for a long time Ransohoff,[1] in 1908, was among the first to record changes in the blood pressure during manipulation of the upper abdominal viscera in man and in animals Recently, Reeve and co-workers[2] have accurately described the respiratory responses to the same type of manipulation The specific stimuli, areas responsive, and pathways of the supposed reflex response were described by these authors In our clinic, arterial hypotension that is coincident with the surgeon s initial exploration of the abdomen has been seen frequently In a one-year period, 92 patients, or 17 5% of 526 who underwent laparotomy, exhibited noticeable falls in blood pressure Although changes in the pulse rate were less obvious than falls in blood pressure, bradycardia was not an unusual finding Since these changes in circulation sometimes occurred in poor-risk patients, and could contribute to postoperative mortality and morbidity, we decided to investigate these phenomena more closely This paper is an account of our efforts to discern the frequency and magnitude of, as well as the stimuli responsible for the circulatory changes

Material and Methods

During the year 1955, whenever possible, patients undergoing abdominal surgery were studied for circulatory responses to abdominal manipulation Sixty-eight patients comprised the group studied, 38 were women and 30 were men All categories of physical status were represented (table 1) Information about the anesthetics given and the types of operations performed may be seen in table 2 The anesthetics were given intratracheally in most cases, and by anesthetists of varying experience

In all patients, continuous observation of the brachial blood pressure was made by means of a Statham P23D strain gauge[2A] attached to a 19-gauge intra-arterial needle, and the information was recorded on a direct-writing Sanborn twin-viso electronic recorder The base line of the recording was checked repeatedly for constancy by reference to the pressure of a water column maintained at heart level Mean arterial blood pressures were obtained electronically in most cases and, in a few, by planimetric integration under the arterial curve In 28 cases, lead 2 of the electrocardiogram was recorded simultaneously with the blood pressure recording Separate electrocardiographic tracings were taken in 22 other cases

Since the possibility existed that changes in circulation might be secondary to alterations in intrathoracic pressure, the recording of data on respiratory activity was followed by the recording of intraesophageal pressure Esophageal pressures approximate intrathoracic pressures The device employed was that recommended by Dr Jeremiah Mead, of Harvard University School of Public Health A plastic catheter, such as is ordinarily used for nasal administration of oxygen, was passed into the esophagus and connected to a Statham P23D strain gauge The pressures were recorded alternately with the electrocardiogram

Another possible explanation for the development of arterial hypotension lay in the increasing depth of anesthesia as surgical exploration was carried out. This is the time when maximal muscular relaxation is needed and anesthetic depth is greatest To make certain of the constancy of anesthetic depth, in 25 cases electroencephalographic monitoring of the level of anesthesia was carried out with fronto-occipital leads on a Grass electroencephalograph

The aforementioned recordings were started early in the course of anesthesia Correlations were made between changes in the records and activity in the surgical field When the peritoneal cavity was entered, a deliberate series of maneuvers was carried out to ascertain the effective stimuli and the areas respon-

Results

Blood Pressure—In 55 of the 68 patients studied, arterial hypotension was observed in relation to abdominal manipulation Only in one case was hypertension seen, and this during upper abdominal exploration in a patient undergoing a pelvic operation under spinal anesthesia Eleven patients showed a negligible drop in blood pressure

In the 44 remaining patients, hypotension was moderate to marked Systolic pressure falls were from 25 to 50% of the immediate prestimulation level The diastolic pressures likewise fell, but to a lesser degree Thus, the mean arterial pressures fell in 44 cases When measured electronically or planimetrically, the average fall in mean pressure in 26 patients was 53 mm Hg On the whole, the higher the initial blood pressure the greater was the relative fall in systolic, diastolic, and mean pressures It may be significant that there was a tendency for the hypotension to be more profound in the patient whose physical status was poor The maximum drop in blood pressure that was observed took place, with exploration, in a 58-year-old man who had essential hypertension and who was undergoing a partial hepatectomy and transverse colectomy for carcinoma The anesthetics consisted of nitrous oxide and ether, followed by deliberate induction of hypothermia to a level of 81 F (27 2 C) The blood pressure fell from 200/105 to 42/20 mm Hg in less than three minutes with manipulation

Relation of Blood Pressure Changes to Nature of Stimuli—The manner in which hypotension was produced is interesting In some cases the change seemed to be clearly reflex in origin That is, with manipulation, with little likelihood of interference with venous return to the heart, and with no change in the depth of anesthesia or accompanying respiratory phenomena, the blood pressure began to fall within a matter of seconds, or within as few as five pulse beats A typical response may be seen in figure 1 A response of this type occurred with application of towels to the peritoneal margins in the incision, with stroking the parietal peritoneum of the anterior abdominal wall in a limited area, or with the initial insertion of the surgeon's hand into the abdominal cavity In some individuals these same stimuli failed to produce the effect The reflex fall of pressure in most cases amounted to 20 mm Hg systolic and 6 mm Hg diastolic over a period of 8 to 15 pulse beats and was transient even if the initial stimulus was continued Repeating the stimulus in another area reproduced the same response The most sensitive areas in this regard were the anterior parietal peritoneum of the upper abdomen, whereas the surfaces of liver, stomach, and viscera were insensitive

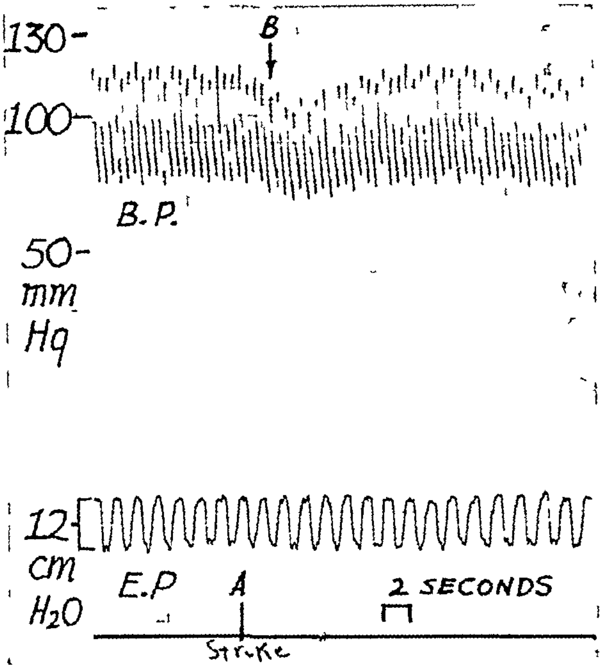

Fig 1 —Continuous arterial blood pressure (upper tracing) and esophageal pressure (lower tracing) in 52-year-old woman undergoing cholecystectomy with nitrous oxide and ether At *A* parietal peritoneum of upper anterior abdominal wall was stroked with small ball sponge Within two seconds, *B*, systolic and diastolic pressures fell Maximum fall was 15 mm Hg systolic and 5 mm Hg diastolic Duration of hypotension was eight seconds There was no change in esophageal pressure

In other cases, although a reflex fall in blood pressure seemed likely, contributing factors could not be eliminated. The fall in blood pressure was of greater magnitude, more prolonged, and failed to return to the previous level in these cases. A step-wise drop in pressure, shown in figure 2, was detected in some of the records. Where the hypotension was marked and persistent and a threat to the patient's welfare, we found that the intravenous injection of atropine was beneficial if the pulse rate was slow. Various measures, such as decreasing the depth of anesthesia, administering sympathomimetic amines, and refraining from surgical activity, brought the pressure back to safe levels in the cases in which the pulse rate was not slow. Displacement of the liver, insertion of the hand into the peritoneal cavity and movement of the hand from one area to another, placement of packing, evisceration, and retraction of the wound edges produced hypotension. Deliberate traction on the mesenteries of the intestine and stomach failed to produce hypotension in several cases. Likewise, stimulation of the celiac plexus was ineffective. Clamping the gallbladder wall and applying traction on this viscus failed, but, even with care taken to avoid obstructing the portal and caval veins, exploration in the common duct region produced a marked response. Of eight patients in whom the vena cava was occluded, four showed no effect and four showed minimal changes.

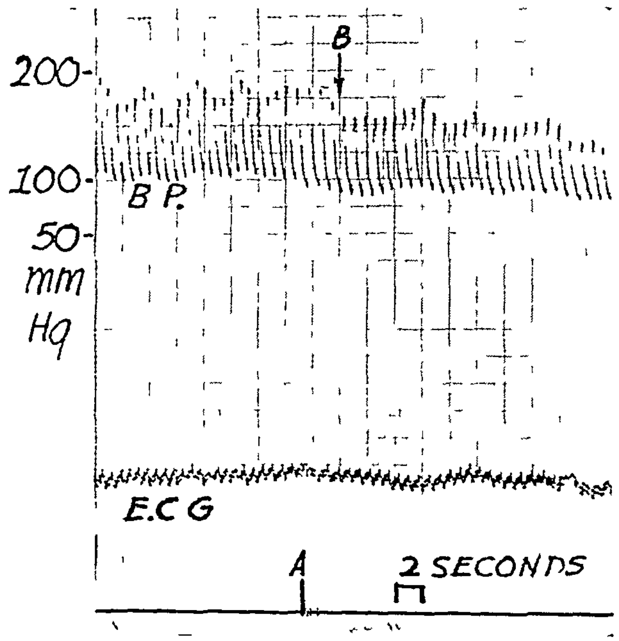

Fig 2.—Continuous arterial blood pressure and electrocardiographic recordings in 70 year-old woman undergoing cholecystectomy and exploration of the common bile duct with nitrous oxide ether, and curare. At A, a hand was inserted in abdominal cavity. Blood pressure fell within two seconds and continued to fall in step-wise manner. There was no change in electrocardiogram.

Electrocardiographic Findings.—The electrocardiographic changes observed from the analysis of lead 2 were by no means as frequent or uniform as the changes in blood pressure. Of the 50 patients studied, 17 exhibited auriculoventricular dissociation with nodal rhythm, or nodal rhythm alone. These abnormalities were associated with a variety of factors in most cases, principally, deeper levels of anesthesia and abdominal manipulation. Practically all were coincident with arterial hypotension. Ether was the common anesthetic agent. More specifically, changes in the pacemaker were coincident with intubation of the trachea, the hypothermic state in two patients, and arterial hypotension under spinal anesthesia. Whether the changes in the pacemaker were reflexly produced, secondary to a decrease in coronary arterial blood flow, or partially responsible for the hypotension cannot be stated.

It would be significant, from the standpoint of explaining the reflex origin of the hypotension, if slowing of the pulse rate and bradycardia were commonly seen. Actually 22 patients evinced a slowing of the pulse rate, 27 showed no change, and 6 responded with an increase. In some cases, slowing of the pulse was coincident with hypotension, in other cases, slowing of the pulse followed hypotension. In all of these the changes took place with manipulation. The pulse rate changes lasted as long as the hypotension. The minimal slowing was 10 beats per minute, with a maximum fall in rate of 36 and an average fall of 16. In five cases, the proportions of bradycardia were reached. The most marked slowing of the pulse took place in two patients with hypotension who were under spinal anesthesia. While bradycardia is a common phenomenon during spinal anesthesia, both the hypotension and change in pulse rate took place in response to a definite surgical maneuver. This suggests a sudden reflex alteration in the circulation, a phenomenon that has been well documented.[3d]

A decrease in the amplitude of the T wave and elevation or depression of the S-T segment were seen in 25 instances in association with manipulation and hypotension or, at other times, in the course of anesthesia and operation. In only one instance was the change pronounced enough to suggest myocardial ischemia. Bearing in mind that only one lead was under observation, this is still striking, in view of the magnitude of the hypotension seen in some cases. No instance of postoperative myocardial infarction was observed in the group studied, although routine electrocardiograms were not taken postoperatively to detect silent infarcts. Two individuals in whom electrocardiograms were taken postoperatively showed T wave and S-T segment changes not present beforehand.

Comment

The function of anesthesia is to block out undesirable reflex responses to surgical manipulation. Ordinarily this implies that the patient's reflex response to pain should be obtunded and that reflex changes in muscle tone should be minimized to provide relaxation. Despite the attainment of these objectives in most instances, other undesirable responses are responsible for many of the difficulties encountered during anesthesia. While skillful management and choice of agents can eliminate some of these, we are not certain that all can be eliminated In the respiratory sphere, breath-holding, bronchospasm, forced expiration, laryngospasm, and hiccough can be troublesome responses to surgical activity, particularly if a light plane of anesthesia is desired Circulatory responses may follow those of the respiration or be elicited purely as arterial hypertension, hypotension, or changes in pulse rate and rhythm We have chosen to study the adverse circulatory response to intra-abdominal manipulation because of its common occurrence and possible relation to postoperative complications

The common response to intra-abdominal manipulation was arterial hypotension, often associated with bradycardia The large percentage of patients with hypotension found in this study contrasts with the usually observed clinical incidence The difference is due, probably, to the methods employed to detect circulatory change Our general impression about hypotension occurring in response to manipulation is that it is solely reflex in nature in some cases and is accentuated by additional factors in others Although hypotension was elicited without change in the depth of anesthesia, as evidenced by the electroencephalograph, the greater the depth of anesthesia the more profound was the fall in pressure We could discern little difference in effect among the various anesthetics employed, though the series was heavily weighted with cases in which ether was used Too few spinal and local anesthetics were employed to allow speculation as to the reflex pathways involved Work is continuing in this sphere, both in man and in laboratory animals The circulatory changes were not related to changes in intrathoracic pressure A great many different stimuli have been implicated in the genesis of these changes Mesenteric traction, celiac plexus stimulation, common bile duct manipulation, and occlusion of the great veins have been mentioned[4] It must be conceded that in few of these prior studies had care been taken to avoid simultaneous stimulation of other receptor zones We cannot provide statistically valid evidence to show which stimulus or which area of the abdomen stimulated may be most responsible The impression gained is that tissue deformation is the basis of all stimuli, that the parietal peritoneum is far more sensitive than the visceral, and that that of the upper abdomen is particularly sensitive It is probable that a fairly limited receptor zone may be responsible in all situations where hypotension is elicited This is suggested further by the work of Reeve and his associates[2] on respiratory responses to manipulation Apnea and laryngeal closure followed intra-abdominal stimulation most frequently when the anterior parietal peritoneum of the upper part of the abdomen was involved

The circulatory response had the characteristics of a reflex The work of others[5] confirms this impression One can only speculate about the receptor, the pathways involved, and the circulatory alterations resulting A likely receptor is the Pacinian corpuscle, which in lower animals and man has a general distribution in the parietes and mesentery[6] The histological appearance of the corpuscle suggests that it may be responsive to deformation[7] Gammon and Bronk[8] recorded an increase in electrical discharges in the afferent nerve of the corpuscle, an increase coincident with the pulse wave in adjacent mesenteric blood vessels It was suggested that the role of the corpuscle is one of local vascular regulation It may be of interest, in this connection, to note that the cardiac arrhythmias associated with cyclopropane anesthesia have been ascribed to reflex action originating in the base of the mesentery[9] The work of Reeve on respiration suggests that the afferent pathway for the circulatory reflexes might be the intercostal nerves, especially if the parietal peritoneum is the sensitive area Further work in laboratory animals and in man must be carried out to assay the role of the phrenic nerve, splanchnic nerves, and vagus nerve in the carriage of afferent impulse from the abdomen Lastly, it seems likely that the vagus nerve forms the efferent limb of the reflex arc and that this alone might be responsible for the hypotension observed The occurrence of bradycardia suggests this, and Peterson[5a] has recently reviewed the evidence to suggest that the vagi may affect ventricular contraction as well Analysis of the pulse wave contour provided some clue as to the circulatory adjustments involved In figure 3 it can be seen that during hypotension there is a flattening of the wave, suggesting a decrease in cardiac output rather than a decrease in peripheral resistance The change in output could be a manifestation of lesser venous filling or decreased cardiac contractility Additional circulatory measurements are required to establish the specific nature of the changes

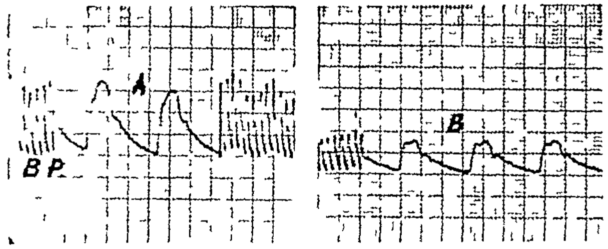

Fig 3—Tracing from the same patient as in figure 2, showing pressure pulse contours *A*, before and, *B* after production of hypotension by intra abdominal manipulation Paper speed has been changed to illustrate the change more clearly Decrease in pulse pressure occurred without change in duration of systole or position of the dicrotic notch This suggests a decrease in cardiac output rather than change in peripheral resistance

The clinical implications of these findings seem clear While we discovered no instance of permanent vascular damage, the magnitude and frequency of the fall in blood pressure indicate that this vascular response may be a real threat to the patient in poor physical status Mendelsohn and Monheit[10] have recently reported a study similar to ours, but one in which more threatening electrocardiographic changes were observed Four patients in their series sustained silent myocardial infarctions It should be added, however, that most of their patients were undergoing gallbladder surgery because of associated heart disease

Summary and Conclusions

The common response to intra-abdominal manipulation during surgery found in this study was arterial hypotension, accompanied by slowing of the pulse rate in most instances These changes were detected in 55 of 68 patients studied by means of recording of intra-arterial and esophageal pressures, electrocardiograms, and electroencephalograms The circulatory alterations had the characteristics of a reflex they seemed to be more profound in the poor-risk patients and were enhanced by deeper levels of anesthesia Further work must be directed toward discovering the means to eliminate these circulatory responses, either pharmacologically or with specific anesthetic agents and techniques

PLASMACYTOSIS AND CRYOGLOBULINEMIA IN CANCER

Milton G Bohrod, M D, Rochester, N Y

• *Cryoglobulinemia in the case here described lasted only a few weeks, and the intense peripheral plasmacytosis lasted only two or three days The patient repeatedly developed well defined wheals in response to five second applications of ice cubes to the skin This urticarial reaction was not obtained in normal subjects, and it was absent in this patient after a radical mastectomy was done to remove an adenocarcinoma The cryoglobulinemia ceased at the same time The evanescent character of these phenomena and their timing with respect to the development of tumors in this patient suggested that they might be interpreted as phases of an immune process in cancer*

It has become apparent in recent years that the phenomena of (1) plasmacytosis, (2) hyperglobulinemia, (3) cryoglobulinemia, (4) amyloidosis, (5) hypersensitivity, (6) collagen diseases, and (7) multiple myeloma are somehow interrelated Some of the relationships that exist among them I have discussed elsewhere,[1] and no more than a summary listing of the principal features will be given here These include the experimental relation of plasma cells to immune body production [2], plasmacytosis in human hypersensitive states [3] and in collagen diseases and the relation of these to hyperglobulinemia [4], and hyperglobulinemia in multiple myeloma, amyloidosis in multiple myeloma [5] and in hypersensitivity states,[1b] and cryoglobulinemia in multiple myeloma and in hypersensitivity states [6] No single feature of this evidence may in itself be weighty, but the combined evidence is striking Somehow these conditions belong together and have a common pathogenic factor or factors as yet unknown Certainly they are all concerned with the broad general concept of immune processes

The relation of multiple myeloma to the other members of the group is a little more evident than the other relationships Apparently the neoplastic plasma cells of this disease are as capable as non-neoplastic plasma cells of producing globulins in excess and of entering into the production of cryoglobulins and amyloid

Every list of the "causes" of plasmacytosis,[7] hyperglobulinemia, or amyloidosis exhibits prominently the various allergic diseases and the collagen diseases There is also a group of miscellaneous rare diseases Practically every such list, however, shows an important group that makes up about 10% of cases or a little less, this is the group of malignant tumors My findings in this group are based on unpublished data on 73 cases of amyloidosis and 7 cases of malignant

---

From the Pathology Laboratories, Rochester General Hospital

Read before the Section on Pathology and Physiology at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956 tumor (exclusive of multiple myeloma) In addition, there were several cases of patients with malignant tumor who also had infection or an allergy, such cases were not counted with the malignancy cases Lately, also, an association between malignancy and collagen diseases, especially dermatomyositis and scleroderma, has been suggested [6]

It is possible that the relationship between tumors and the group of phenomena mentioned above is fortuitous or through mechanisms of entirely unrelated kinds But it cannot be denied that there exists in patients with neoplasms something that in the broadest sense must be called immunity [8] It seems desirable, therefore, to explore this possible relationship between immunity in cancer and the other phenomena associated with immunity The case cited below affords a striking illustration of the directions in which such exploration could take place

Report of a Case

A 68-year-old woman went to her physician on Feb 16, 1954, because she thought she had a lump in her left breast He failed to find one and noted that she had no abnormal signs or symptoms She had been hypertensive for at least 15 years, but at the time of her examination her blood pressure was 130/70 mm Hg Two weeks later she reported she had passed a good deal of blood through her rectum Proctoscopic examination was negative except for clotted blood that was seen high up in the sigmoid Six days later the patient had a cold and fever Her lungs were edematous, and she was thought to be in acute heart failure Antibiotics were given

A few days later, on March 12, 1954, she entered the hospital X-ray examination showed pulmonary congestion and cardiomegaly with 25% enlargement There was a single density in the first anterior rib A barium enema and air contrast studies revealed no organic disease of the colon The hemoglobin level was 8 Gm per 100 cc, with red blood cells numbering 4,720 000 per cubic millimeter and white blood cells 13,150 per cubic millimeter, comprising 40% neutrophils, 44% lymphocytes, and 4% eosinophils A few of the lymphocytes were called Turk s irritation cells With therapy with mercurial diuretics the patient improved and went home in nine days

She entered the hospital again on Sept 28, 1954 She had been in good health until she had caught a cold while on a trip She had a sore throat, running nose, and nonproductive cough She was given one injection of penicillin and some sulfonamides The patient was in mild heart failure Her abdomen was somewhat distended The liver was four fingerbreadths and the spleen two fingerbreadths below the costal margin There were small shotty lymph nodes in the anterior cervical chain and a single firm discrete node in each axilla A firm, but not hard mass 2 cm in diameter was found in the mid-upper part of the left breast

On Sept 27, the day before her second entrance into the hospital, the patient s white blood cell count had been 27,000 per cubic millimeter, with a preponderance of lymphocytes many of which were said to have been abnormal On Sept 29, her white blood cell count was 53 600 per cubic millimeter, with 42% of the cells typical plasma cells, numbering 22,500 per cubic millimeter An additional 6% of the cells (3,200 per cubic millimeter, which is about normal) were normal lymphocytes The red blood cell count and hemoglobin level were normal The platelet count was normal, numbering 320,000 per cubic millimeter An examination of the iliac crest bone marrow on the same day showed a large number of plasma cells in an otherwise normal marrow

Blood studies on the same day disclosed that the level of total proteins was 7 5 Gm per 100 cc, serum albumin, 3 8 Gm per 100 cc, and serum globulin, 3 7 Gm per 100 cc Gamma globulin was 1 33 Gm per 100 cc, the normal for the chemical method employed being 0 71-1 14 Gm per 100 cc The levels of nonprotein nitrogen, uric acid, and glucose, as well as the icterus index, were normal The blood serum was described as slightly lipemic An electrophoretic pattern was not available at that time Gross inspection of the excess serum, which had been in the icebox overnight, showed a whitish precipitate occupying the lower third or less of the test tube (fig 1) The association of plasmacytosis with a precipitate in the cold serum suggested a cryoglobulinemia When the cold serum was warmed to 37 5 C, all but a trace went back into solution, when cooled, precipitation again occurred Tests during the next several days, during all of which cryoglobulin was demonstrable, showed that it was necessary to collect serum in warmed syringes and test tubes and to keep it warmed to 37 5 C if precipitation were to be avoided If these precautions were not taken, a precipitate was noted almost immediately, if they were, the serum was perfectly clear and not lipemic

The urine contained a faint trace of albumin Repeated examinations failed to show any Bence Jones protein, and this absence continued Cold agglutinins and autoagglutinins could not be demonstrated The Coombs test was negative Reexamination of the x-rays elicited the opinion that the so called rib lesion noted on the patient s first entrance to the hospital in March, 1954, had really been in the lung and had cleared up There were no lesions in the skull or spine

The patient was questioned concerning skin lesions and reaction to cold She revealed that 40 and again 20 years before she had had attacks of "hives" which she related to eating peaches and which apparently were not associated with cold For a few days before her second entrance to the hospital in September, 1954, she had had a hives-like eruption on the upper arms and at the margins of the breast, which was present only in the morning and disappeared during the day She also had noted (when asked if cold caused her any trouble) that cold water or other cold liquids gave her difficulty in breathing and a sense of pressure behind the upper sternum and that these symptoms were relieved by drinking warm water Because of this, she said, she always kept herself warm and ate only warm foods The morning after this history was obtained an urticarial rash appeared and was photographed It was more extensive than it had been before, being present also on the lower thighs and knees (fig 2)

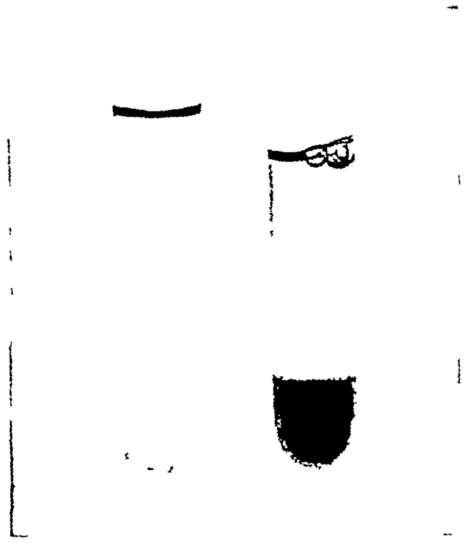

Fig 1 —Cryoglobulin in blood serum In the tube on the right, a precipitate is present after refrigeration In the one on the left, a similar precipitate has been dissolved by warming to 37 5 C

The next day, Oct 1, the patient s white blood cell count was down to 24,900 per cubic millimeter, and fewer cells were plasma cells On Oct 4, the white blood cell count was 17,300 per cubic millimeter, with almost no plasma cells After that time, no plasma cells were found and none were seen during any of the very many blood examinations taken in the following 18 months

On Sept 29 a cold skin test was taken in the following way A cylindrical ice cube was pressed against the skin of the anterior surface of the patient s forearm for five seconds only

Within two minutes a well-defined wheal exactly the size of the ice cube appeared, followed by the appearance of ameboid streamers outward at the periphery (fig 3) The test was repeated several times during the following few days, and it was consistently positive in the patient The same test performed on a large number of persons, both male and female, failed to elicit any reaction except, in one case only, a faint redness Previous tests of this sort have used longer application times up to one or two minutes, and have because of this, been more difficult to interpret More reactions are obtained in normal subjects with these longer times but such reactions frequently consist of redness rather than urticaria

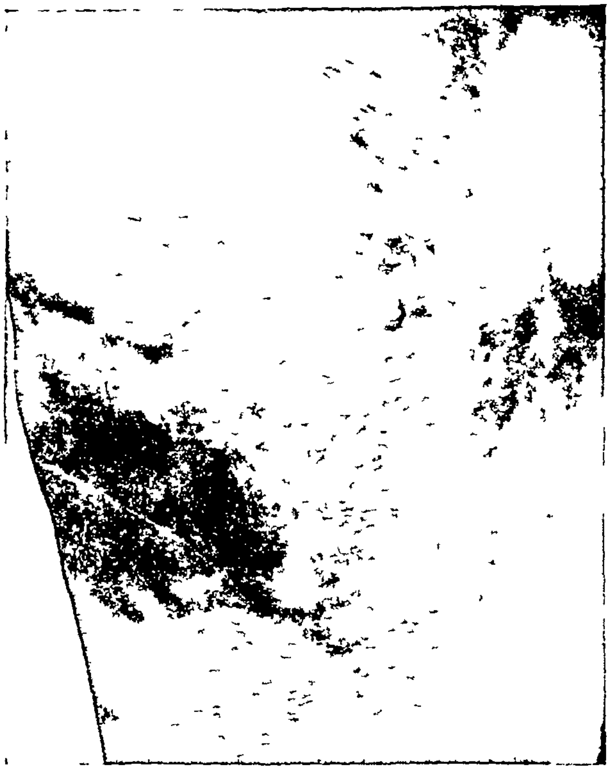

Fig 2 —Urticaria, anterior surface of knee The rash was present on successive mornings but disappeared by early afternoon

On Oct 1 biopsy specimens of the breast lesion and of a left axillary lymph node were taken The breast lesion was an adenocarcinoma the lymph node showed no evidence of tumor but did show a moderate plasmacytosis A gingival biopsy specimen taken at the same time showed no evidence of amyloidosis On Oct 11 a radical mastectomy was done No more tumor tissue was found either in the breast or in axillary lymph nodes Plasmacytosis was much less marked than at the time of the biopsy Cryoglobulins were found all during the patient's stay in the hospital She was discharged on Oct 17 The next examination for the presence of cryoglobulins was two and one-half months later none were found Coincidently with this the application of ice to the skin no longer elicited urticaria For the next 16 months the patient was well and repeated examinations for cryoglobulins Bence Jones protein, and plasmacytosis, made at three to six month intervals, were negative

On April 15 1956 the patient entered the hospital with evidence of an intestinal obstruction On May 7 an adenocarcinoma of the sigmoid was removed The lymph nodes showed no evidence of carcinoma and only a mild plasmacytosis There was no peripheral plasmacytosis, and the bone marrow was normal Blood proteins were normal On one occasion, several days postoperatively, there was one mild attack of urticaria On May 16 she had an eruption on the skin that resembled erythema multiforme On that day an ice cube test on the skin was negative On that day and the next there was a very small amount of cryoglobulin demonstrable, but on the following day it was gone

Comment

Every pathologist is aware of the frequency with which a small malignant tumor is surrounded by a zone of lymphocytes and plasma cells that separate the tumor from deeper normal tissue Kidd[8] has shown in transplanted tumors that the ability of a transplant to penetrate deep into surrounding tissues and to spread and metastasize is correlated in his animals with the disappearance of the lymphoid cells In the broadest sense of the term this plasmocellular barrier may be called an immune process For a long time it has been thought that immune processes in malignant tumors may be entirely different from those already known for inflammatory disease and against foreign proteins Observations that relate malignancy to plasma cells and globulin metabolism should, however, revive the hope that immunity in cancer has some, at least, of the features of other immune mechanisms and may, therefore, be susceptible to the similar methods of attack

Most studies of plasmacytosis and cryoglobulinemia have indicated that these states generally last a considerable time The case of cryoglobulinemia described by Steinhardt and Fisher,[9] which they were tempted to call essential cryoglobulinemia because no underlying disease state was found, lasted over three years My case is notable for the short duration of these phenomena—weeks for the cryoglobulinemia and two or three days at most for the very intense peripheral plasmacytosis On the appearance of the patient's second carcinoma a small amount of cryoglobulin was present for only two days Plasmacytosis has been thought of as an unusual phenomenon and, in the large

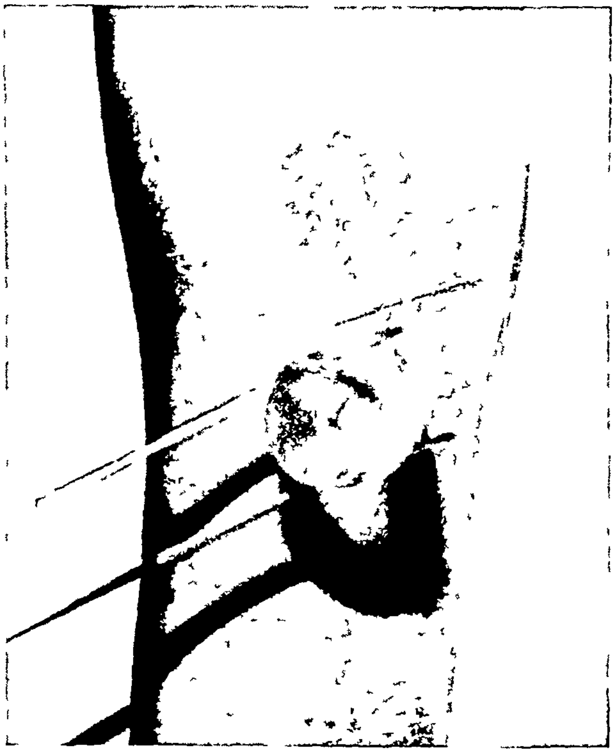

Fig 3 —An induced urtica on the anterior surface of the forearm after application of ice for five seconds

amounts in the peripheral blood of my patient, a rare finding, cryoglobulinemia has up to now been seen only rarely If, however, they may be as evanescent as in the present case, may we physicians not be dealing with phenomena that seem to be uncommon only because they are easily missed? Certainly it was luck that enabled me to pick out the three days of this patient's plasmacytosis and obtain the peak determination One cannot often expect to be so lucky in a chronic disease

There can be no relationship between the plasmacytosis and the removal of the cancer, since the plasmacytosis had disappeared before the tumor was removed There is less certainty about the relation of the mastectomy to the disappearance of the cryoglobulinemia Only repeated observations on other cases will determine this

Summary and Conclusions

A case of cryoglobulinemia and very marked peripheral blood and bone-marrow plasmacytosis was seen in a patient whose only other apparent disease was a small carcinoma of the breast The principal symptomatic manifestations of the cryoglobulinemia were urticaria that was present only in the morning and intolerance to cold and the swallowing of cold fluids The urticaria could be induced at the site of application of ice to the skin These manifestations lasted only for short times, the cryoglobulinemia disappeared some weeks after mastectomy, the plasmacytosis lasted only three days and had disappeared before the operation The relation of cryoglobulins and plasma cells to immune processes should be considered, and there may be a relation between these and similar factors to what may broadly be called immunity in cancer The demonstrated evanescent or short-lived character of these phenomena in one case suggests the possibility that they may not be so uncommon in cancer as well as in other conditions, as has been supposed and that it may be worthwhile to look for both cryoglobulins and plasma cells by frequent examinations

Digitalis Overdosage—The arrhythmias resulting from digitalis overdosage usually disappear spontaneously, if the drug is discontinued Treatment for arrhythmias is ordinarily not necessary If digoxin was used, they disappear within two to three days, if digitoxin was given, the arrhythmias may persist for from two to three weeks In some instances of supraventricular tachycardias, ventricular premature beats, or ventricular tachycardias induced by digitalis, however, specific treatment may be needed In these cases, the oral administration of potassium chloride, acetate, or citrate usually eliminates the arrhythmias within 30 minutes Two to 10 grams of a 20 per cent solution may be given in syrup of citric acid or Karo syrup, or smaller quantities may be given in milk, orange juice, or ginger ale Administration of 5 to 10 cc of Potassium Triplex (Eli Lilly) in orange juice (5 cc contains 0 5 gm each of potassium acetate, potassium citrate and potassium carbonate) is also efficacious, but its effect lasts only for from two to four hours The treatment may, therefore, have to be repeated Toxic effects due to the potassium do not occur, if there is adequate urinary excretion Rarely is it necessary to administer potassium intravenously, if it is, extreme caution should be used, and only 0 5 to 1 5 gm should be given slowly Electrocardiograms should be taken frequently, to detect potassium intoxication Its most common effect is marked peaking of the T-waves, widening of the QRS complexes, and disappearance of the P-waves That potassium depletion may sensitize the myocardium to the toxic effects of digitalis has recently been proved Conversely, the presence of adequate cellular potassium should usually prevent toxic digitalis effects For these reasons, potassium should usually be given to patients who require large doses of digitalis Arrhythmias may thereby be prevented Orange juice has a relatively high potassium content and may be efficacious in combating digitalis intoxication —A M Master, M D, Heart Failure Its Treatment—with Special Reference to Chronic Lung Disease, *Diseases of the Chest*, November, 1956

HYPERPHOSPHATASEMIA IN PATIENTS WITHOUT JAUNDICE WITH HEPATOBILIARY DISEASE

Thomas B Gibbons, M D , Seattle

• *The presence or absence of either hepatic metastasis or common bile duct pathology in anicteric patients can be predicted with a high degree of accuracy by determination of the serum alkaline phosphatase level Studies were carried out in 234 cancer patients and in 190 patients with gallbladder disease When the test was done preoperatively in 103 patients with intraabdominal malignancy, normal values were obtained in 65, and only 4 of these were found at operation to have hepatic metastases elevated values were found in 38, and 32 of these proved to have hepatic metastases A similar association of hyperphosphatasemia with hepatic metastases was found in 56 patients with extraabdominal malignancy The alkaline phosphatase level was also helpful in gauging the progress and prognosis of 75 patients with previously resected neoplasm Among 81 anicteric patients tested before cholecystectomy, the alkaline phosphatase accurately predicted the status of the common bile duct in 74 and was of comparable value in evaluating 89 patients whose gallbladder had previously been removed Comparison of this test with direct bilirubin and the sulfobromophthalein tests showed it to be the most accurate of the three in the detection of either hepatic metastasis or obstruction of the common bile duct in patients free of jaundice*

The value of determination of the serum alkaline phosphatase level in the differential diagnosis of jaundice is well established However, its remarkable usefulness in patients without jaundice with certain clinically important types of hepatobiliary disease seems less widely appreciated

In the fall of 1953, I had two patients with diagnostic problems in whom determination of the serum alkaline phosphatase level proved valuable in directing attention to the presence of hepatobiliary disease One patient was a middle-aged male acutely ill with pneumonia but with a history of weight loss over the preceding two months His alkaline phosphatase level was elevated and he was found to have bronchogenic carcinoma with pneumonitis in the lobe involved and with hepatic metastases The other patient was an elderly female with weight loss and digestive disturbances whose alkaline phosphatase level was very high and who was found to have choledocholithiasis, although neoplasm had been suspected clinically Neither patient had jaundice

Although aware of the association of hepatic metastasis and hyperphosphatasemia, I had not used the test extensively for the detection of neoplasm in the liver I had been totally unaware of the ability of stones in the common bile duct to cause elevation of the serum alkaline phosphatase level in the absence of jaundice Therefore, it was decided to explore further the behavior of the phosphatase level in patients without jaundice in whom carcinoma or gallbladder disease had been proved or was suspected The results of this investigation make up the material for this report and, as will be seen, confirm the value of the determination of the alkaline phosphatase level in detecting neoplasm in the liver Of greater interest and importance is the remarkable significance of the serum phosphatase level in the prediction of the presence of stones in the common bile duct despite the absence of jaundice

Value of Determining Alkaline Phosphatase Level

Alkaline phosphatase, an enzyme that liberates inorganic phosphorus from phosphoric esters, is found in largest concentration in the body at sites of glucose transfer (intestinal mucosa and renal tubules) and bone formation (osteoblasts) The serum alkaline phosphatase arises largely, if not entirely, from the bones[1] and, in man, appears to be excreted only by way of the bile As a result, any impairment of biliary drainage causes retention of phosphatase and an increased concentration of the enzyme in the plasma For this reason, determination of alkaline phosphatase level has come to be used as a test of the excretory function of the hepatobiliary system

Roberts,[2] in 1930, first noted elevation of the serum alkaline phosphatase level in patients with jaundice and later pointed out its usefulness in differentiating parenchymal from obstructive forms of icterus Subsequently, determination of the alkaline phosphatase level has been employed almost exclusively in patients with jaundice and for the evaluation of various disorders of bone

In 1937, Flood and co-workers[3] called attention to the value of the alkaline phosphatase level in the detection of the presence of hepatic metastases by reporting on 20 patients with neoplastic liver disease, 17 of whom had hyperphosphatasemia These authors noted that the phosphatase level often rises before jaundice appears The following year, Meranze and co-workers[4] stressed the usefulness of determination of the alkaline phosphatase level in the preoperative evaluation of patients with carcinoma and reported elevation of the phosphatase level in 15 out of 16 patients without jaundice with hepatic metastases Since then, there has been only an occasional report dealing with the topic[5] In 1954, Shay and Siplet[6]

From the Department of Medicine of the Mason Clinic and the Virginia Mason Hospital Dr Gibbons is now in Albuquerque, N Mex

Read before the Joint Meeting of the Section on Gastroenterology and Proctology and the Section on Pathology and Physiology at the 105th Annual Meeting of the American Medical Association Chicago June 14 1956 suggested employing determination of the alkaline phosphatase level in the follow-up observations of patients with a previously resected neoplasm.

My experience has confirmed the accuracy of the determination of the alkaline phosphatase level in the early detection of neoplasia in the liver in patients without jaundice. I have employed it routinely for the preoperative detection of hepatic metastases in patients known to have cancer. This knowledge has often influenced the decision as to the type and extent of surgery to be employed in attacking the primary lesion. The test has been of assistance, for both prognostic and diagnostic purposes, in the follow-up observation of patients operated on previously for cancer. I have also found the test of considerable diagnostic help in a variety of puzzling clinical problems that proved eventually to be due to cancer. Exemplifications of this are patients with an unidentified lung shadow shown by roentgenogram or a gastric ulcer that could be malignant or with a constricting lesion in the descending colon that might be diverticulitis or neoplasm. Too often an elevated alkaline phosphatase level has been the first definite clue to the presence of a cancer of the body or tail of the pancreas. Unfortunately, the patient whose tumor is first diagnosed by means of determination of the alkaline phosphatase level is already beyond cure because of liver involvement.

The situation is decidedly more encouraging with reference to common bile duct pathology. In my experience, the alkaline phosphatase level is extremely sensitive to the presence of any impediment of extrahepatic biliary drainage such as results from the presence of stones in the common duct of a patient without jaundice. I have come to rely rather heavily on the determination of the alkaline phosphatase level, ordering it taken routinely on patients for whom cholecystectomy is planned. If the phosphatase level is elevated, the surgeon is forewarned that exploration of the common bile duct will probably be required. Similarly, the test is helpful when one is confronted with a patient with digestive symptoms or abdominal distress whose gallbladder has previously been removed. I consider an elevated phosphatase level in a patient who has undergone cholecystectomy compelling evidence for the presence of organic common duct pathology, such as stones, partial stricture, or sphincter fibrosis.

I am unaware of any detailed analysis of the relationship between the alkaline phosphatase level and extrahepatic biliary disease in patients without jaundice. Standard textbooks of medicine and gastroenterology refer to the phosphatase level in discussing jaundice but do not stress its usefulness in the preoperative prediction of ductal stones in patients without jaundice with gallbladder disease or in the evaluation of patients with postcholecystectomy symptoms.

In 1938, Freeman and co-workers[7a] reported a rise in alkaline phosphatase level in dogs without jaundice after ligation of the hepatic ducts draining part of the liver. In 1940, Gutman and co-workers[7b] confirmed the dissociation of normal plasma bilirubin and hyperphosphatasemia in dogs after ligation of branches of the hepatic duct system and stated that incomplete obstruction of the common bile duct by cholangitis or choledocholithiasis could cause an elevation of the phosphatase level without jaundice. However, this suggestion has apparently been largely overlooked and the value of the serum alkaline phosphatase level in detecting incomplete extrahepatic biliary obstruction without jaundice has not, to my knowledge, been widely employed.

Within the last few months a renewed interest in the problem of diagnosing common duct pathology in the absence of jaundice has been evident. The general impressions gained by the present study were briefly presented earlier this year by Stone.[8] Shortly later Watson[9] reported the value of the direct-reacting bilirubin level in a variety of conditions including choledocholithiasis, and Culver and co-workers[10] have recently described their experience with hyperphosphatasemia in six patients without jaundice with partial obstruction of the common bile duct.

Material

During the years 1954 and 1955, the period of this study, serum alkaline phosphatase levels were determined one or more times in 1,033 adults without jaundice. Patients with jaundice, scleral icterus, or a total serum bilirubin level in excess of 2.5 mg per 100 cc, regardless of the clinical description, are not included in this report. The serum alkaline phosphatase level, determined by the King-Armstrong method, was normal (13 King-Armstrong units or less) in 728 patients and was elevated in 305.

TABLE 1.—*Causes of Hyperphosphatasemia in Patients Without Jaundice*

Cause	Cases, No.
Hepatic metastases	95
Common bile duct pathology	80
Parenchymal hepatic disease	38
Bone disease	26
Chronic passive congestion	16
Unexplained	20
Not investigated	30
Total	305

Table 1 lists in order of decreasing frequency, the various causes of hyperphosphatasemia. Despite the absence of jaundice in the patients, diseases of the hepatobiliary system accounted for the elevation of alkaline phosphatase level in 70% of the total. By contrast diseases of bone associated with hyperphosphatasemia occurred only 26 times, or 8.5%, and included 10 patients with osteoblastic metastases usually *prostatic in origin*, 7 with *osteitis deformans* (Paget's disease of bone), 5 with healing fractures, and 4 with hyperparathyroidism.

Sixteen patients with passive congestion of the liver due to heart failure were found to have mild to moderate hyperphosphatasemia, ranging as high as 43.5 King-Armstrong units, with a mean value of 19.0 units in patients without jaundice. In 20 patients a reason for the elevated phosphatase level could not be found, and in 30 patients the clinical investigation was, for various reasons, judged inadequate to exclude all the usual causes of an elevated phosphatase level.

Metastases to the liver accounted for 72% of the 133 instances of hyperphosphatasemia without jaundice due to intrahepatic disease. Other causes were as follows: cirrhosis 20, cholestasis due to chlorpromazine 7, diabetes with fatty liver 5, anicteric hepatitis, 4, and collagen disease, 2. The second most commonly encountered cause for hyperphosphatasemia in patients without jaundice was pathology of the common bile duct, usually ductal stones.

TABLE 2.—*Preoperative Determination of Phosphatase Level in 103 Patients Without Jaundice with Intra-abdominal Malignancy*

Alkaline Phosphatase Level	Cases, No.	Hepatic Metastases	
		Present	Absent

Elevated	38	32	6

Patients with Hepatic Metastases

The alkaline phosphatase level was determined in 234 patients without jaundice with cancer. The test was done preoperatively in 103 patients with intra-abdominal malignancy (table 2). Of 65 patients with a normal preoperative phosphatase level, only 4 had hepatic metastases. Six patients were encountered who had a normal phosphatase level and no metastases in the liver but who had small surface implants on the liver as a part of generalized peritoneal carcinomatosis. Four of these neoplasms originated in the ovary, and in three patients the absence of intrahepatic lesions was subsequently confirmed at autopsy.

By contrast, of 38 patients with hyperphosphatasemia preoperatively, 32 had gross metastases visible and palpable in the liver at the time of operation. In six patients there were no detectable metastases, although deep intrahepatic lesions may have been present. The preoperative phosphatase level, therefore, proved accurate in predicting hepatic metastases in at least 90% of this group of patients without jaundice with cancer in whom the liver could be examined at operation.

A determination of alkaline phosphatase level was obtained preoperatively in 56 other patients with forms of cancer that did not require abdominal surgery (table 3). The phosphatase level was normal in 36 patients, none of whom had any clinical evidence to suggest involvement of the liver. The phosphatase level was elevated in 20 patients with extra-abdominal malignancy, 15 of whom had clinical signs of probable liver metastases as evidenced by hepatomegaly or a progressively rising phosphatase level and deterioration. In five patients there was no hepatic enlargement, and follow-up observations through the period of this study gave no definite indication of neoplasia in the liver.

TABLE 3.—*Determination of Phosphatase Level in Fifty-six Patients with Extra-abdominal Malignancy*

Alkaline Phosphatase Level	Cases, No.	Hepatic Metastases	
		Present	Absent
Normal	36	0	36
Elevated	20	15 (probable) 5 (possible)	0

In order to better assess the patient's status and the prognosis of his condition, the alkaline phosphatase level was determined in an additional 75 patients without jaundice who had previously undergone operation for cancer (table 4). The phosphatase level was normal in 38 patients, none of whom had detectable hepatomegaly or other clinical evidence to suggest the spread of neoplasm to the liver. However, 37 patients without jaundice operated on previously for cancer were found to have hyperphosphatasemia. Hepatic metastases were demonstrated in nine of these patients by liver biopsy, autopsy, or exploration of the abdomen. In 19 cases, hepatic metastases were judged probably present on the basis of hepatomegaly, progressive deterioration of the patient's condition, and, in many cases, a progressive rise of the serum phosphatase level. Liver involvement was further suggested in a number of these patients by the later development of jaundice. Seven patients had an elevated phosphatase level but no clinical stigma to suggest hepatic metastases, although in some cases spread or recurrence of neoplasm was evident elsewhere in the body.

The mean alkaline phosphatase level for patients with proved metastasis to the liver was 24.1 King-Armstrong units. For patients considered, on clinical grounds, as probably having malignant involvement of the liver, the mean value was 30.5 units. There was no apparent relationship between the degree of hyperphosphatasemia, which ranged from 13.5 to 84.5 King-Armstrong units, and the extent of neoplastic replacement of liver. Furthermore, it seemed clear that even a small increment of serum phosphatase bodes ill for the patient with cancer, since some cases of metastatic liver involvement were encountered in which patients had phosphatase levels only one or two units above the normal limit. Actually, as Shay and Siplet[6] have pointed out, the phosphatase level in the adult is remarkably constant from month to month. In following patients with previously resected neoplasms, I have encountered instances of gradually rising phosphatase levels still within the normal range, which, nevertheless, in retrospect, probably denoted early liver involvement, since hyperphosphatasemia and obvious hepatic metastases developed later.

TABLE 4.—*Determination of Phosphatase Level in Seventy-five Patients Without Jaundice Who Had Previously Undergone Surgery for Cancer*

Alkaline Phosphatase Level	Cases, No.	Hepatic Metastases	
		Present	Absent
Normal	38	0	38
Elevated	37	9 (proved) 19 (probable) 7 (possible)	2

The neoplasms resulting in the hepatic metastases seen in this study were usually primary in the digestive system. The distribution was as follows: colon, 12 cases; stomach, 12; breast, 11; pancreas, 6; rectum, 4; bronchus and liver, 3 each; and prostate, gallbladder, and lymphosarcoma, 2 each. Other widely scattered primary sites accounted for the remainder of the carcinomas found to be metastatic in the liver and associated with hyperphosphatasemia without jaundice

Patients with Diseases of the Biliary System

The serum alkaline phosphatase level was obtained in 178 patients without jaundice with disease of the extrahepatic biliary system, either current or previous Prior to cholecystectomy the phosphatase level was determined in 81 patients (table 5) Of 50 patients with a normal phosphatase level, 5 were found to have stones in the common bile duct, although operative cholangiograms in 3 of them did not disclose dilatation of the duct and the stones may have entered at the time of anesthesia or surgical manipulations The phosphatase level was misleadingly normal in the other two patients who had stones, a dilated duct, and, in one, a history of previous jaundice In the other 45 patients with a normal preoperative phosphatase level, the biliary tree was normal at operation

In 31 of the patients tested before cholecystectomy, the preoperative phosphatase level was elevated, and in all but 2 of these *the common bile duct was abnormal* Twenty-six patients had stones in the common bile duct, none were icteric and only three gave a history of previous jaundice Three patients had a dilated, thickened duct but no stones were recovered, presumably the stones had passed between the time the phosphatase level was determined and the time of operation An excellent example of this was provided by a patient with an alkaline phosphatase level of 27 King-Armstrong units and three stones in the common bile duct demonstrated by intravenous cholangiography This patient did not come to operation until two months later, at which time his preoperative phosphatase level was found to be normal At operation the common bile duct was likewise found to be normal, the previously proved ductal stones having passed in the intervening period of time

The test was applied in 89 patients who had had cholecystectomy performed months or years previously (table 6) Not all of these patients had symptoms at the time of the test, but it was done as part of this study and as a screening procedure to find stones in asymptomatic patients The phosphatase level was normal in 48 patients in the group, most of whom were asymptomatic *In 10 of* the patients with a normal phosphatase level, an intravenous cholangiogram was done because of strongly suggestive symptoms In nine, the duct was found to be normal by cholangiography, but in one case dilatation, stones, and delayed emptying of the duct were found

TABLE 5 —*Determination of Phosphatase Level in Eighty one Patients Without Jaundice Before Cholecystectomy*

Alkaline Phosphatase Level	Cases No	Common Bile Duct	
		Normal	Stones
Normal	50	45	5
Elevated	31*	2	26

* 3 patients had dilated duct but no stone

Hyperphosphatasemia without jaundice was encountered in 41 patients whose gallbladder had previously been removed In all of the 31 cases investigated, an abnormality of the common bile duct was found At subsequent operation, 25 patients had ductal lithiasis and 3 had a partial stricture, while in the remaining 3 patients a prosthesis was known to be in place In 10 patients with an elevated alkaline phosphatase level, exploration or intravenous cholangiography has not yet been done

Normal	48	47*	1
Elevated	41†	0	25(stones) 3(stricture) 3(prosthesis)

* Corroborated by intravenous cholangiogram in 9
† 10 cases not yet investigated

Liver biopsy was performed at the time of operation in several of the patients without jaundice with hyperphosphatasemia due to stones in the common bile duct No instances of biliary cirrhosis were encountered Occasionally there was pathological evidence of recent ascending cholangitis, but in most patients the liver was normal histologically

The alkaline phosphatase level was also found elevated in a small group of patients without jaundice with external compression of the common bile duct Narrowing of the duct was confirmed in each case by operative cholangiography The various causes of the duct compression were as follows malignant lymphadenopathy without hepatic metastases three cases, pancreatic cyst, three, and pancreatic fibrosis, two In summary the alkaline phosphatase level was determined in 121 patients without jaundice who had surgical examination of the biliary tree In an additional nine cases, the ductal system was checked by intravenous cholangiography alone Determination of the phosphatase level enabled the physician to predict accurately the presence or absence of common duct pathology, usually stones, in 94% of these patients

The mean phosphatase level in patients without jaundice with ductal stones who were tested before cholecystectomy was 35 5 King-Armstrong units, within a range of 15 0 to 80 0 units The patients with common duct pathology after cholecystectomy had an average phosphatase level of 33 4 King-Armstrong units and a range of 14 0 to 75 9 units Patients with jaundice due to stones in the common bile duct who were encountered during the study period averaged only a slightly higher phosphatase level of 38 0 units In contrast, malignant obstruction with jaundice tended to cause a greater rise in serum phosphatase level, with an average of 57 7 King-Armstrong units The patients with jaundice are not included in the present report

During this study the technique of intravenous cholangiography with use of sodium iodipamide (Cholografin sodium) became generally available This procedure was employed in 25 of these patients In nine, both the alkaline phosphatase level and the intravenous cholangiogram were normal In one patient with normal phosphatase level, referred to previously, the cholangiogram demonstrated stones in the common bile duct, and in one case the reverse was true Of an additional three patients with hyperphosphatasemia, the cholangiogram failed to demonstrate stones but did reveal a dilated duct with delayed emptying in two of the patients, while in one the duct system was not visualized by the dye In the remaining 11 patients, the ductal stones predicted by the elevated phosphatase level were confirmed by the intravenous cholangiogram and subsequently by operation

Other Liver Function Tests

Other liver function tests have been suggested for the purpose of detecting partial intrahepatic obstruction of biliary drainage Shay and Siplet[6] recommended combining the sulfobromophthalein sodium retention test with determination of the alkaline phosphatase level in order to enhance the accuracy of diagnosing hepatic metastases Watson[9] has recently discussed the particular value of determining the direct reacting bilirubin fraction in patients without jaundice with various types of hepatobiliary disease, including hepatic metastases and stones of the common bile duct

TABLE 7—*Comparative Value of Liver Function Tests*

Pathology Present	Test Employed	Patients No	Patients with Abnormal Test %
Hepatic metastases	Determination of alkaline phosphatase level	45	91
	Direct bilirubin	19	78
	Sulfobromophthalein	22	73
Obstruction of the common bile duct	Determination of alkaline phosphatase level	73	93
	Direct bilirubin	55	64
	Sulfobromophthalein	13	62

In table 7 the comparative value of these tests for detecting hepatic neoplasia and partial obstruction of the common bile duct in the present study is shown Only pathologically proved cases of metastases are included in this comparison If the patients classified on clinical grounds as probably having hepatic metastases are included, the total number becomes 79, but the accuracy remains essentially the same for determination of the phosphatase level, at 92% All diagnoses of common duct pathology were substantiated by operation

In my experience, determination of the alkaline phosphatase level is more accurate than the direct serum bilirubin or sulfobromophthalein sodium retention tests in detecting either hepatic metastases or common duct pathology The direct bilirubin test was performed by the method of Powell[11] and values above 0 15 mg per 100 cc considered abnormal Sulfobromophthalein sodium retention was measured 45 minutes after injection of 5 mg of dye per kilogram of body weight, with 5% taken as the limit of normal retention Sulfobromophthalein sodium retention and direct-reacting bilirubin tests were abnormal in about three-fourths of the patients with hepatic metastases and in approximately two-thirds of those with common duct pathology By comparison, the serum alkaline phosphatase level was elevated in more than 90% of the patients in both categories

Of the four patients with metastases in the liver and a normal phosphatase level, none had had serum bilirubin determinations done and only one had had a sulfobromophthalein sodium retention test, which was also normal Of the six patients with stones of the common duct and a normal phosphatase level, a direct-reacting serum bilirubin test was done in four, with normal results in every case The sulfobromophthalein sodium retention was determined in one case and was slightly abnormal at 6%

It should be mentioned here that during this study I encountered one patient with jaundice due to stones of the common duct whose alkaline phosphatase level was normal In all other patients with such stones and jaundice, hyperphosphatasemia was present as expected Likewise, all patients with jaundice due to hepatic metastases had a high alkaline phosphatase level (average 70 5 King-Armstrong units) None of the patients with jaundice are included in this report

The serum cholesterol level is sometimes elevated in patients with obstructive jaundice or biliary cirrhosis In this study, determinations of cholesterol level were done in only a few of the patients without jaundice with metastasis or stones of the common duct No instances of definite hypercholesteremia were encountered However, a serious shortcoming of determination of cholesterol level as a test of biliary patency is its wide range of normal concentration, thus making the individual cholesterol level difficult of interpretation An additional test, which, unfortunately, was seldom performed, is for bilirubin in urine An occasional positive test was encountered, but not consistently As will be brought out later, the urine bilirubin test theoretically should be positive in all patients with an elevated alkaline phosphatase level due to partial biliary blockade without jaundice

Precautions

In my experience, the presence of hyperphosphatasemia in a patient without jaundice has usually been due to either neoplastic involvement of the liver or common duct pathology, generally ductal lithiasis However, less frequent causes for the elevated phosphatase level do occur, as was shown in table 1 Cirrhosis or hepatitis occasionally result in hyperphosphatasemia (average values 17 5 and 23 9 King-Armstrong units respectively) without jaundice, but other tests of parenchymal liver function and, especially, the history and physical examination will usually permit recognition of these disorders Previous treatment with chlorpromazine (Thorazine) hydrochloride must also be kept in mind in evaluating a patient with hyperphosphatasemia without jaundice During the present study, I encountered seven such patients with an average phosphatase level of 27 0 King-Armstrong units Cholestasis without jaundice due to chlorpromazine has recently been reported[12]

In my patients with metastatic liver disease or ductal stones, tests of parenchymal cell status were almost always normal *Nearly all patients had either a* thymol turbidity test or a cephalin-cholesterol flocculation test, and, in many, more detailed liver tests were done An occasional patient with extensive metastatic replacement of the liver or recent cholangitis had slightly abnormal parenchymal tests, but in the vast majority they were normal If the liver profile shows significant alteration of parenchymal cell function or if the clinical picture presented suggests parenchymal liver disease, the presence of an elevated alkaline phosphatase level in a patient without jaundice should not be regarded as proof of either metastases in the liver or partial biliary obstruction

Diseases of bone characterized by attempts at bone regeneration, such as osteitis deformans, osteomalacia, fracture, osteoblastic osseous metastases, and some cases of hyperparathyroidism, can cause an elevated alkaline phosphatase level Roentgenographic studies of the skeleton together with determinations of calcium, phosphorus, and acid phosphatase levels, plus the clinical picture presented by the patient, will ordinarily lead to the proper diagnosis However, isolated osseous metastases or localized forms of osteitis deformans might be overlooked and cause erroneous incrimination of the hepatobiliary system

Congestive heart failure can, at times, cause an elevated phosphatase level, apparently as a result of passive congestion of the liver [3] Heart failure is usually readily apparent clinically but should be kept in mind when evaluating the condition of a patient with hyperphosphatasemia without jaundice Two physiological causes of an elevated phosphatase level are pregnancy and the bone growth of childhood The latter does not present much difficulty, since hepatic metastases and choledocholithiasis are seldom encountered in children However, it should be recalled that there is often an elevated phosphatase level, presumably placental in origin, during the third trimester of pregnancy [13] I found hyperphosphatasemia in 3 of 12 pregnant women tested during the course of this study The three with an abnormal phosphatase level were in the third trimester

In most cases of metastatic disease of the liver, the primary lesion is demonstrable by physical examination or x-ray techniques However, I have, on a number of occasions, been unable to locate the site of origin of a neoplasm suspected to be present by reason of an elevated phosphatase level Abdominal exploration in these patients has always demonstrated hepatic metastases, and often the primary lesion was found in the pancreatic body or tail As Shay and Siplet [6] have pointed out, the presence of sulfobromophthalein sodium retention in conjunction with elevation of the phosphatase level enhances the reliability of diagnosis of hepatic metastases In my experience, as in Watson's,[9] the same holds true for the direct-reacting serum bilirubin test and also applies to the diagnosis of stones of the common bile duct in patients without jaundice However, as was shown in table 7, the sulfobromophthalein sodium retention and direct bilirubin tests were abnormal in a decidedly smaller percentage of the patients with either metastasis to the liver or biliary tree pathology than was the determination of the alkaline phosphatase level

In all of my patients with choledocholithiasis, either the gallbladder had been removed in the past or, if the gallbladder was intact, the presence of cholelithiasis or nonfunction of the viscus was demonstrable by roentgenographic studies That is, no patient with choledocholithiasis had a normal cholecystogram The newer method for intravenous cholangiography now provides a valuable method for confirming the presence of common duct patholølgy It has not proved any more accurate than the determination of phosphatase level for this purpose, and, of course, there is no comparison between the methods in terms of time involved, technical complexity, cost to the patient, or general availability

Comment

The mechanism of hyperphosphatasemia without hyperbilirubinemia in patients with space-occupying intrahepatic lesions, such as metastases, is unknown Three theories have been suggested (1) retention of phosphatase due to interference with normal excretion of this enzyme in the bile, (2) overproduction of phosphatase by the liver, and (3) unknown alterations of the plasma resulting in an increased phosphatase activity as measured in the laboratory

To test for the presence of an unknown phosphatase activator, equal parts of plasma from a normal subject and plasma from a patient with hyperphosphatasemia without jaundice were mixed The phosphatase level determined on the mixed specimen after incubation was not higher than the expected average of the two Histochemical techniques have failed to demonstrate alkaline phosphatase in cancers originating in tissue other than bone, except for small amounts in the connective tissue stroma,[14] nor is there conclusive evidence that the liver produces the excess phosphatase found in patients with hepatic metastases, although some observers believe that regenerating cholangiolar epithelium is a source of phosphatase [15]

An appealing explanation for the dissociation of hyperphosphatasemia and normal bilirubin level in patients with either intrahepatic or extrahepatic partial biliary obstruction is provided by the retention theory, which is strengthened by the results of animal experimentation Ligation of subdivisions of the extrahepatic biliary tree in dogs [7] results in an elevated serum phosphatase level and bilirubinuria, but the total serum bilirubin level remains normal Regardless of the level of serum phosphatase, the dog does not excrete this enzyme in the urine Cats, on the other hand, do excrete phosphatase via the kidneys, and in the cat a ligature around the bile duct does not result in hyperphosphatasemia [16]

One of my patients with colic and indigestion two years after cholecystectomy was found to have an elevated phosphatase level without jaundice Intravenous cholangiography demonstrated a solitary stone in the left hepatic duct The common duct was free of stones and not dilated The situation in this patient would seem to be comparable to that described above in dogs with hepatic duct ligatures, and, like the dog, man does not lose phosphatase in the urine However, bilirubin of the direct-reacting variety does escape into the urine at a very low renal threshold, about 0 5 mg per 100 cc It is thought, therefore, that the loss of bilirubin in the urine prevents a partial biliary obstruction from causing jaundice but that phosphatase is retained in the plasma since it is unable to pass the renal barrier Whether or not the retention theory, which depends upon the differential renal excretion of bilirubin and phosphatase, is correct, it offers an explanation compatible with the clinical findings reported

Since the completion of this study, Culver and coworkers[10] reported on a series of six patients without jaundice with pathology of the common bile duct, either stone or stricture, who had hyperphosphatasemia To explain the dissociation of phosphatase and bilirubin, these authors suggested that the partial obstruction of the biliary system raised the back pressure in the liver sufficiently to interfere with the excretion of phosphatase but not of bilirubin by the parenchymal liver cells I prefer to consider the passage of phosphatase from plasma to bile to be more of a passive process largely independent of parenchymal cell activity, since most patients with severe parenchymal cell dysfunction and many with acute yellow atrophy of the liver do not have any elevation of serum phosphatase level

Despite the lack of a generally accepted explanation of hyperphosphatasemia without jaundice, the data presented adequately demonstrate that this dissociation does occur in patients with partial biliary blockade and that the phenomenon may be put to good use clinically

Summary and Conclusions

Determination of the serum alkaline phosphatase level is a remarkably accurate gauge of the presence of stones in the common bile duct or hepatic metastases in patients without jaundice When the determination is done prior to cholecystectomy, the phosphatase level, if elevated, gives warning that exploration of the common duct and drainage will probably be required The test also assists in the evaluation of the condition of patients with postcholecystectomy symptoms, since the phosphatase level is rarely normal if organic pathology of the duct, such as stones, stricture, or ampullary fibrosis, exists even though jaundice is absent In my experience, this test has been fully as accurate as intravenous cholangiography in evaluating biliary tree patency

Similarly, management of cancer patients is facilitated by determination of serum alkaline phosphatase level Hyperphosphatasemia is a sensitive and early indication of metastatic spread to the liver, while a normal phosphatase level offers reassurance that the neoplasm has not yet involved the liver Used preoperatively, determination of the phosphatase level can assist in planning the type and extensiveness of surgery to be done Employed in patients with a previously resected neoplasm, the test helps gauge progress and prognosis Also, this test is occasionally valuable as a screening procedure for neoplasia and at times is the only clue to the presence of an occult neoplasm, such as carcinoma of the body of the pancreas

In conclusion, the results of this investigation confirm the definite usefulness of determination of the serum alkaline phosphatase level in patients without jaundice with disorders of the common bile duct or metastatic involvement of the liver As is true of any laboratory procedure, the results of the test must be evaluated in light of the over-all clinical picture

PERSONAL TECHNIQUE AND RESULTS IN INGUINAL HERNIA REPAIR

Amos R Koontz, M D, Baltimore

• In 436 patients who had an operation for inguinal hernia, the recurrence rate was 0 46% The almost 100% cure rate is possible when any of the many types of procedures are performed by thoughtful surgeons who are willing to vary the operation to fit the anatomy of their patients The important thing is for the surgeon to realize the importance of exercising infinite care and pains in every single step of the operation, no matter how inconsequential the hernia may seem to be

That inguinal hernias may be repaired successfully by a number of different methods is being demonstrated every year A recent summary [1] of the various methods being used, taken from personal reports from 286 of the leading surgeons of the country, amply illustrates this Undoubtedly some of these reports were influenced by personal prejudices for or against certain methods I feel sure, however, that, on the whole, these eminent surgeons were setting forth unbiased and unprejudiced views based on a wide and thoughtful experience

Undoubtedly too many surgeons early in life adopt a method of inguinal hernia repair, which they use routinely without giving any thought to varying their methods to suit the individual case One reason for this is poor training, which undoubtedly, and lamentably, still exists in some of our hospitals Another reason is that very often even able chiefs of service turn hernia operations over to the junior members of their house staffs, because they feel, if only subconsciously, that the operation is of little importance The young house men are given entirely too much leeway in the choice of the operation and are not properly supervised in the actual technique of the method employed The fact has been impressed upon me in many hospitals, both civil and military, in this country and abroad, that the younger the surgeon the more fixed his ideas are apt to be and the poorer his results This has resulted in a great deal of careless and sloppy work in hernia repair, and I believe that it is responsible for the still too large number of recurrences that we have throughout the country

In spite of this, when the operation is carefully done, there are many methods which will effect a number of cures, approximating 100%, when these methods are used by thoughtful surgeons, without fixed ideas, who are willing to vary the operation to fit the anatomy of their patients The late Dr J M T Finney was frequently heard to say "Make your operation fit the patient Don't try to make the patient fit your operation" The importance of this maxim is realized by all surgical philosophers And how can a man really be a surgeon unless he is a philosopher? No matter how beautiful one's surgical technique may be, he does not meet the yardstick of the surgeon unless he has a knowledge of the techniques of other surgeons and the judgment to evaluate the good and bad points of those techniques

Methods of Operation

It would be presumptuous to speak of any method as "the" method In this paper I propose simply to recount some of the methods I have used with a high degree of success in inguinal hernia repair There are, of course, other methods which have been successfully used However, I believe that it is highly important for us to reevaluate the subject occasionally and put more thinking and less dogmatism into it Dogmatism seldom has a place The recent study referred to above shows that it has little, if any, place in inguinal hernia repair

Figures 1 to 6 illustrate some of the methods I have used in operating for this condition There have been various variations of these methods Frequently only one part of the techniques depicted in the illustrations is used in a particular case The legends under the illustrations describe the methods Various points, however, will be discussed below

Handling of the Sac —It is axiomatic that in indirect inguinal hernias there should be a high ligation of the sac This can readily be done in primary indirect inguinal hernias where the neck of the sac is narrow A simple transfixion and ligation is simply and easily done However, in large indirect inguinal hernias and especially in recurrent hernias, the base of the sac is often very broad and a simple transfixion and ligation cannot be done In these cases the sac should be dissected free, excised, and the peritoneum closed with a running suture of silk or cotton (fig 1)

In many instances the LaRoque [2] incision is most valuable in dealing with the sac This is especially true in the case of patients with sliding hernias and with recurrent hernias, in whom the anatomy has been 'scrambled' by previous operation and the relationships of the various structures are hard to determine through an inguinal incision In these cases the La Roque incision is a great timesaver This is a simple muscle-splitting incision, made about 1 in above the internal ring, entering the peritoneal cavity at that point By means of a finger in the peritoneal cavity, the relationships of the sac can be readily determined, the nature of the hernia can be ascertained, and the other usual sites of groin hernia explored in order to determine whether more than one hernia is present In recurrent hernias this method is a great help in unscrambling the anatomy, which has frequently been so badly distorted by many previous operations (I have operated on a good many hernias that had been operated on as many as six times before, and in one case the poor patient had had seven previous opera-

---

From the departments of surgery of the Johns Hopkins University School of Medicine and the Johns Hopkins Hospital

Read before the Section on Surgery, General and Abdominal, at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956 tions[1]) In sliding hernias this method provides an easy method of dealing with the condition and converts what in many cases is a difficult operation into an easy one Those not familiar with this method of dealing with the sac in sliding hernias should lose no time in becoming so

In the majority of direct inguinal hernias the sac is dome-shaped and not excessively large In such cases it is not necessary to open the sac but the sac may simply be tucked in by puckering interrupted or mattress sutures If the sac is large it is best to open it dissect it free and excise it The opening in the peritoneum is closed with a running suture of black silk In the occasional direct hernia instead of the sac being dome shaped owing to a general weakness of the transversalis fascia, it is pear-shaped and protrudes through one weak spot in Hesselbach's triangle which is surrounded by strong transversalis fascia Such a sac may be dealt with by transfixion and ligation

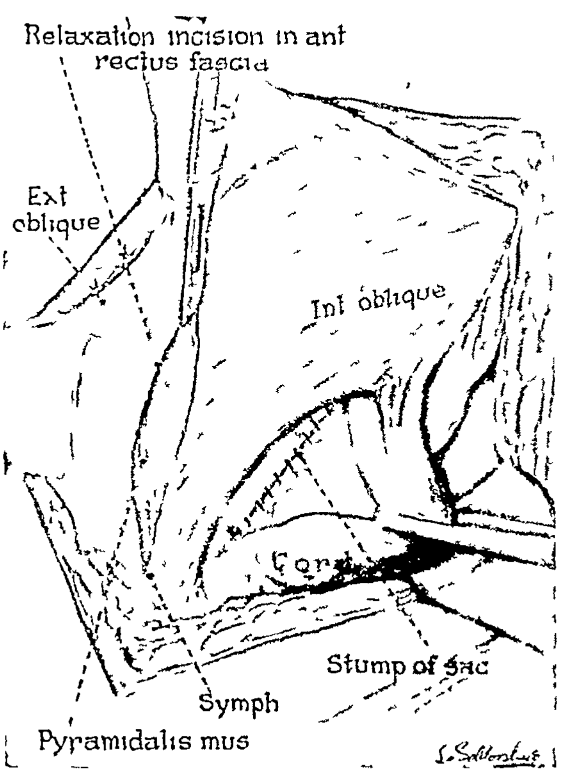

Fig 1—Sac of large scrotal hernia has been resected and peritoneum closed with running suture of silk Relaxation incision is being made in sheath of rectus muscle from symphysis pubis upward for approximately 3 in This incision is not perpendicular but is slightly diagonal tending in lateral direction the higher it goes in order to conform to insertion of aponeurosis of external oblique into rectus sheath Incision should be made as close to this insertion as possible If it is made near lateral border of rectus muscle a weak spot will be left just lateral to muscle when various structures are sutured together during plastic repair

When one is dealing with what is obviously a direct hernia one must be sure that there is not an associated indirect hernia This should always be carefully searched for If there is any doubt about the presence or absence of an indirect sac, a LaRoque incision should be made, and the entire groin area explored from within the peritoneal cavity for the presence of either an indirect or a femoral sac Often a small indirect sac cannot be palpated with the examining finger However, with a LaRoque incision the abdominal wall at the lower edge of the incision can be lifted with a retractor, and the internal inguinal ring inspected as well as palpated[3]

Closing the Hole in the Transversalis Fascia—In direct inguinal hernias frequently the floor of the inguinal canal is strong (especially in young patients) except for the opening in the transversalis fascia through which the sac protruded After the sac has been disposed of, the hernia may be cured by simply closing the opening in the transversalis fascia snugly around the cord (fig 3) This can best be done if the cord is lifted from its bed, so that the entire floor of the inguinal canal can be inspected It should also be palpated, not only from the outside but from the inside as well This can be done with a finger in the abdominal cavity through the open sac At the same time the possibility of any direct or femoral hernia can be determined Undoubtedly a great many hernias can be cured simply by closing the hole in the transversalis fascia However, I believe that it requires rare judgment to determine just which cases come in this category It must be remembered that the patient would not have a hernia at all did he not have a tendency to some weakness in his fascia, or were he not put together a little bit more loosely than the normal person Realizing that he has this tendency, one must consider what may further happen to him as the years go by

Some authors advocate simply closing the opening in the transversalis fascia in the repair of direct inguinal hernias As a rule, a direct inguinal hernia is due to a thinning out of the transversalis fascia in the entire Hesselbach triangle area In these cases the transversalis fascia is not strong enough to effect a cure by simply closing it There are a few cases, however, in which the fascia in Hesselbach's triangle is strong except for one small area through which a direct hernia protrudes, having a sac resembling an indirect sac in shape rather than the usual dome-shaped affair which is generally encountered Possibly simply closing the hole in the fascia in these instances would cure the hernia However, it is my feeling that more should be done in the way of a plastic repair in these cases

Relaxation Incision in the Sheath of the Rectus Muscle—The relaxation incision in the sheath of the rectus muscle, first described by Halsted[4] in 1903 in one small paragraph of an article on hernia repair and since lucidly described by Fallis,[5] Rienhoff,[6] and Tanner,[7] is a valuable adjunct to any form of plastic repair and provides relaxation of the tissues which cannot otherwise be obtained I use it almost routinely in the repair of inguinal hernias in adults The inner flap of the aponeurosis of the external oblique is dissected free from the sheath of the rectus by blunt finger dissection In recurrent hernias this often requires sharp dissection The aponeurosis is then elevated with a retractor, and an incision in the rectus sheath is made just lateral to the insertion of the external oblique aponeurosis into the rectus sheath The incision should extend from the symphysis upward for about 3 in (fig 1, 3, 4, and 5) As a rule, in making the incision one small vessel is severed Both ends of this should be ligated with transfixion ligatures Ordinary ligatures may slip and cause bleeding (I learned this the hard way In closing an incision a few years ago, blood started welling up from below I had to open the wound and found that a ligature had slipped on a vessel which had been cut in making the relaxation incision) Immediately the relaxation incision is made the edges of the fascia separate for about 1 in , which is a great factor in relieving tension in any plastic repair Indeed, if only a hole is to be sutured in the transversalis fascia, this relaxation incision seems worthwhile

The question is often asked, Will not such an incision weaken the abdominal wall? It will not if the incision is made at the proper place and as far mesially as the attachment of the aponeurosis of the external oblique to the rectus sheath will permit If the incision is made toward the lateral edge of the rectus muscle, the suturing of the structures in the plastic repair will pull the sheath away from the lateral edge of the muscle, leaving a very weak spot there with nothing but transversalis fascia and peritoneum, as the posterior sheath of the rectus is absent below the semilunar line of Douglas Halsted,[4] in reflecting a flap of the sheath of the rectus to strengthen Hesselbach's triangle, pointed out that such a reflection of the flap left a weak spot at the lateral edge of the rectus It is true that this weak spot is covered by the aponeurosis of the external oblique, and Davis has found that it causes no trouble in using the Halsted flap operation Be that as it may, it is simple to make the relaxation incision over the belly of the muscle itself, where it certainly causes no trouble It has been demonstrated experimentally[8] that in such cases the rectus sheath undergoes regeneration

Position of the Cord —I was brought up on the Ferguson-Andrews operation[9] (also called the Halsted II[4] and the Hopkins operation) for indirect inguinal hernia and on the Bassini operation for direct inguinal hernia In the Ferguson-Andrews operation the cord is left in its bed, the conjoined tendon sutured to Poupart's ligament over it, and the flaps of the aponeurosis of the external oblique are overlapped Because I felt that there were too many recurrences with the Ferguson-Andrews operation, I abandoned it and started using the Bassini operation routinely for both direct and indirect inguinal hernias I soon gave this up also and for 20 years or more have been transplanting the cord almost routinely in adults into the original Halsted subcutaneous position This allows a tight and complete closure of the lower end of the canal and, I believe, gives a better chance of preventing a direct recurrence than if the cord is left in either the Ferguson or the Bassini position Even young adults, who at the time of their hernia repair seem to have strong fascia in the floor of the canal, suffer a thinning out of these structures in middle or old age with a tendency to develop direct hernias A tight closure of the lower end of the canal helps to obviate this Besides, interposing the cord between layers of good supporting abdominal wall interferes with the growing together of such structures as the internal and the external oblique, and it seems reasonable to believe that these united structures will form a firmer buttress against intra-abdominal pressure than if they have the cord interposed between them It has been shown[1] that this position of the cord has become the most popular among leading surgeons of the country for large indirect inguinal hernias and also for direct hernias

An objection that is often raised to the subcutaneous transplantation of the cord is that it destroys the obliquity of the canal It is true that the canal is oblique to start with But if the oblique canal does not prevent the occurrence of a hernia, how can the preservation of its obliquity prevent the recurrence of the hernia? It must be remembered that, in order for an indirect hernia to recur, it must first emerge through the internal ring If that emergence occurs, the recurrence is a *fait accompli*, and the position of the external ring has no bearing on this already accomplished fact

Another objection that has been raised to the subcutaneous transplantation of the cord is that it might cause some tenderness in this position in thin persons I have never seen this occur, and I have not been able to find any surgeon who has seen it occur I have occasionally, in operating for bilateral inguinal hernia transplanted the cord in the subcutaneous position on one side and in the Bassini position on the other side None of these patients was ever aware of any difference in the two sides

Removal of the Testis —The only reason for removing the testis is to dispense with the cord Probably the presence of the cord is the greatest obstacle to the cure of inguinal hernia in the male patient This structure is undoubtedly responsible for the far greater number of inguinal hernias in male than in female patients In spite of this, I believe that most inguinal hernias in male patients can be cured without sacrificing the cord Some surgeons refuse to operate on difficult recurrent hernias unless the patient agrees to the sacrifice of the testis on that side I no longer ask patients before operation if they are willing to have a testis removed Most of them flatly refuse or accede to the request with great reluctance In an occasional case in recurrent hernias, the cord comes through the internal ring through a mass of scar tissue, sometimes of such a cartilaginous consistency that proper closure of the structures around the cord is impossible, and it is felt that the presence of the cord would invite another recurrence In such cases the cord may simply be transfixed and ligated at both the internal and the external ring, and the intermediate portion resected Unless the testis has been removed from its bed, the collateral circulation to that organ will not have been interfered with, and atrophy is rare In those patients in whom atrophy does occur, it is probable that the cord has been dissected free too far beyond the external ring, thus interfering with the collateral circulation After such an excision of a section of the cord, some swelling and tenderness of the testis occurs, but this condition generally subsides within a few days A suspensory should be worn during the troublesome period

Reducing the Size of the Cord—Reducing the size of the cord is highly important, so that the internal ring may be closed snugly around as little tissue as possible Large cords can be greatly reduced in size by removing the cremaster and any fatty tissue or lipomas which are in the cord (fig 1, 2, and 3)

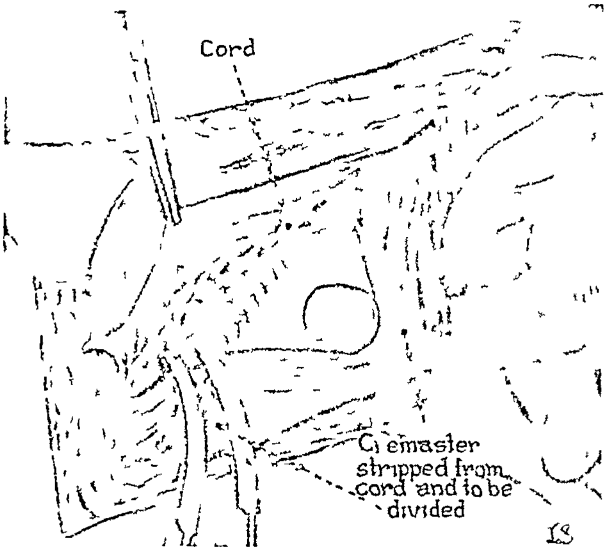

Fig 2 —In large hernias cremaster is generally considerably hypertrophied Here it is being separated from rest of cord in order to reduce size of cord at internal ring and thus enable better approximation of tissues around cord in that area Any lipomas or fatty tissue in the cord should also be removed

Closing the Internal Ring—I believe that a great many hernias recur because the structures forming the internal ring are not closed snugly enough around the cord In most cases there would be no indirect hernia in the first place if the structures had not been lax about the cord at the internal ring In repairing the hernia, the structures around the internal ring should be closed tightly enough to prevent a new hernia sac from impinging itself between these structures and the cord This requires a very tight closure It is difficult to close the internal ring tightly enough to interfere seriously with the circulation of the testis That, however, is a calculated risk which every surgeon has to take if he expects to cure an indirect inguinal hernia and save the cord Unless he does close the structures tightly, he may expect a recurrence Atrophy of the testis is rare even with a very tight closure of the internal ring The method of Lytle, in which the cord is fixed to the edge of the internal ring by suture (fig 4) to prevent a new hernia sac from being dragged down by traction on the cord, seems to have merit

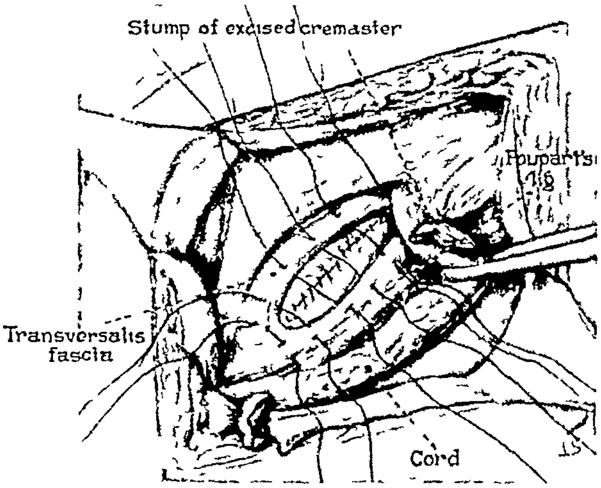

Fig 3 —Transversalis fascia being closed This should be closed carefully in all cases It is much stronger in some cases than in others It should be closed snugly around cord at internal ring

Removal of Extraneous Tissue—Before any type of plastic repair is attempted, all extraneous tissue, such as cremaster, areolar, or adipose tissue, should be thoroughly cleaned out of the canal Also, all adipose and areolar tissue should be removed from any structures to be used in the plastic repair This is highly important It has been demonstrated experimentally[10] that areolar or other intervening tissue between sutured structures results in a thin, filmy, flimsy type of union, instead of the good solid union that can be obtained if such intervening material is removed before the structures are sutured together

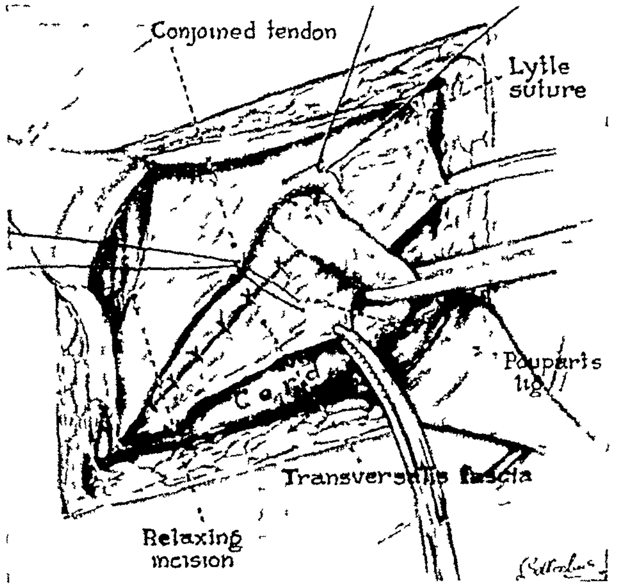

Fig 4 —Transversalis fascia has been closed In those cases in which it is bulging, it should be converted into a flat surface by puckering sutures A Lytle suture is being placed above internal ring, approximating structures about cord there and transfixing some tissues of cord in order to prevent a dragging down on peritoneum by that structure, thus possibly producing a new hernia Conjoined tendon is about to be sutured to Poupart's ligament This is done only in those patients in whom it is felt from the nature of the anatomy, that the closure would be stronger by so doing

Conjoined Tendon—If the conjoined tendon is to to be used in the repair (fig 4), one should be able to bring it down to Poupart's ligament without tension This can readily be done in most instances by using the relaxation incision in the sheath of the rectus muscle If the transversalis facia is strong and the opening in it has been well closed, it seems hardly necessary to bring the conjoined tendon to Poupart's ligament If it seems to the surgeon that the closure would be stronger by so doing, though, there is no reason for not doing it Each case is an individual case, and the use of the structures used in the plastic repair should be made to the best advantage on an individual basis I seldom find it necessary or advantageous to suture the conjoined tendon to Poupart's ligament, even when it is felt that the transversalis fascia might become weakened at some later date In these cases a piece of tantalum gauze used to reinforce the entire area has proved to be sufficient

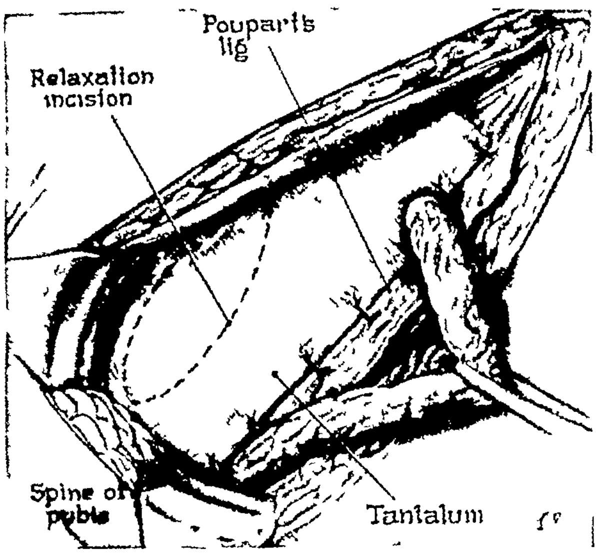

Fig 5—Entire area, including the relaxation incision in sheath of rectus has been reinforced by a piece of tantalum gauze The size of this piece is generally 4 5 to 5 in long by 2 to 2 5 in wide Only lower or outer edge is sutured to Poupart's ligament with interrupted sutures of silk It is not necessary to turn edges under Mesial, or inner, edge should be cut so as to fit snugly into line of fusion of aponeurosis of external oblique to sheath of rectus However, it should not be too wide, or buckling will ensue when edges of aponeurosis of external oblique are approximated Sutures are unnecessary, except as shown, because aponeurosis of external oblique, when put back into its normal place, securely holds tantalum gauze in place

Tantalum Gauze—Tantalum gauze has been proved to be most efficacious in those patients who have tissue deficiencies or very weak tissues It has the advantage over fascia flaps of not giving trouble in the presence of infection[11] Fascia flaps slough out if infection is encountered, while tantalum gauze remains in place and the resultant cure is just as strong as if there had been no infection Tantalum gauze is especially valuable in recurrent hernias When I first used it in inguinal hernia repair, I used a very small piece—a long narrow strip just wide enough to cover the first suture line (conjoined tendon to Cooper's ligament) This resulted in a recurrence Later I used it simply to cover the Hesselbach triangle area[12] In one patient in whom it was so used in repairing a direct hernia, an indirect hernia appeared a year or two later Possibly enough attention was not paid to closing the internal ring at the first operation Since then I have been using the method depicted in figure 5, using the gauze to cover the entire hernial region and making a snug V-shaped vent for the cord at the internal ring

Aponeurosis of External Oblique—In their original operations both Halsted and Bassini simply approximated the edges of the two flaps of the aponeurosis of the external oblique in making their closures The edges of these two flaps were first overlapped by Lucas-Championnière, of France The procedure was popularized in this country by E Wyllys Andrews, of Chicago After him, the practice of imbricating the flaps of the aponeurosis became pretty general here I used it routinely for years I have abandoned the practice (fig 6), however, except in those few cases in which the flaps are so loose that the imbrication may be accomplished without any tension As a rule, this is not the case, and the flaps cannot be overlapped without tension This is highly undesirable Anyway, especially in large hernias with poor tissues, the external inguinal ring is large and the aponeurosis of the external oblique is poor in that area, so that successful overlapping is difficult or impossible in the area where strength is most needed Furthermore, the roof of the inguinal canal is not the important part in preventing a hernia recurrence It is obvious that the floor is the important part and that, if the floor is not strong, a recurrence is invited If a new hernia appears through the floor of the canal, the patient already has his hernia, no matter how strong the roof is In those patients with poor tissues the floor of the canal can be strengthened by the use of tantalum gauze, as indicated above Then it does not become highly important to depend upon the overlapping of a weakened aponeurosis of the external oblique in the Hesselbach triangle area to reinforce that region

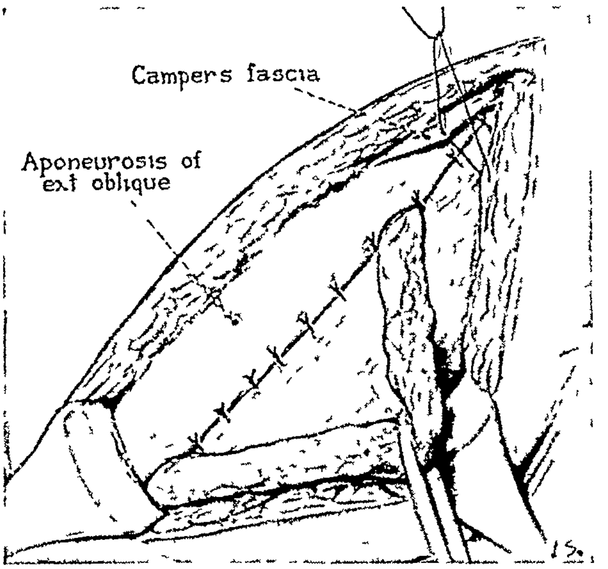

Fig 6—Aponeurosis of external oblique has been closed with interrupted sutures of silk Operation is now finished except for closing subcutaneous tissue and skin Former is closed with interrupted sutures of fine silk, and latter, with fine silk continuous sutures

Cooper's Ligament Repair—The method of Cooper's ligament repair was first used by Lotheissen[13] in 1898 It has recently been popularized in this country by McVay and Anson[14] After publication of the latter authors first paper on the subject, the method was pretty universally tried here There is reason to believe that it is not now as widely used as it formerly was,[1] although a few surgeons use it routinely The method is a lifesaver in certain types of tissue defects, but I believe that its routine use is improper anatomically, in spite of the seemingly logical argument of McVay and Anson that to suture the conjoined tendon to Poupart's ligament is to transpose fascia planes, the conjoined tendon being in the same fascia plane as Cooper's ligament, while Poupart's ligament is in the same fascia plane as the fascia lata and the aponeurosis of the external oblique Even so, when the fascial structures are strong in Hesselbach's triangle, those structures have to be disrupted in order to expose Cooper's ligament, so as to suture the conjoined tendon to it This seems to me undesirable It is true that some surgeons suture the conjoined tendon to Cooper's ligament without exposing the ligament This is an improper procedure for two reasons In the first place, if intervening structures are left between the conjoined tendon and Cooper's ligament, firm healing cannot be expected[10] In the second place, there are frequently aberrant vessels in this area, which may be punctured by blind suturing and cause severe hemorrhage or even the external iliac vein itself may be injured I use the Cooper ligament repair in those patients in whom the anatomic findings are such that I believe the repair will be stronger with the use of Cooper's ligament than it would be with the use of Poupart's ligament This seems to me to be the crux of the situation— to get the strongest repair, no matter what structures are used in making the repair The Cooper ligament repair is ideal in those patients in whom the inguinal ligament has been cut at a previous operation or in whom it is weak or frayed I use it routinely in operations for recurrent femoral hernia

Suture Materials.—Silk and cotton are the popular suture materials for hernia repair in this country I strongly feel that they are the best suture materials (now available) in all clean surgical cases There is very little choice between the two materials Both keep structures in apposition until strong healing takes place, and both give trouble in the presence of infection I believe that it can be categorically stated that absorbable surgical suture (catgut) should never be used as a suture material in hernia repair The success of the repair depends upon having the important structures, which are sutured together in making the repair, stay in apposition until firm healing takes place Harvey and his co-workers have shown that it takes 10 to 14 days for such healing to occur The wound does not become firmly consolidated until about two months after operation It has been amply demonstrated that the tensile strength of absorbable material in buried sutures is variable and that in a great many cases it cannot be depended upon to hold structures in apposition until firm healing takes place Parsons reported that the recurrence rate at the Presbyterian Hospital in New York was four times as great when absorbable surgical suture was used as when silk was used The statement is frequently made that the former is better now than it was 20 years ago This is unquestionably true However, Madsen[15] has recently made extensive studies on suture materials In a comparison of silk and chromic absorbable sutures, he found that, when those sutures were placed in fascia, they initially had the same tensile strength After six days the silk sutures maintained their initial tensile strength in nine out of nine cases, whereas only three out of nine chromic absorbable sutures were reliable Madsen also showed, as had been amply demonstrated before,[16] that there was a marked cellular reaction around the absorbable sutures In view of these findings, it seems to me that it is only to court disaster to use absorbable surgical suture as a suture material in hernia repair It is true that some of the patients in whom this material is used will remain cured, but the incidence of recurrence is much higher

Some surgeons still raise objection to using silk or cotton, claiming that they cause trouble in the presence of infection and often a persistent sinus tract This is unquestionably true However, frequently the offending silk or cotton suture may be fished out with a crochet needle or with a very small ear curet If this method is not successful, it seems to me far more desirable to have to open an occasional sinus tract under local anesthesia and remove an offending suture than to run the risk of the large incidence of recurrences which one unquestionably runs in using nonabsorbable sutures

In order to obviate the trouble that silk or cotton causes in the presence of infection, some surgeons use stainless steel wire as suture material in hernia repair I do not believe that this is desirable because of the tendency of the wire sutures to cut through the tissues Furthermore, I have recently operated on two patients with recurrent hernias, in both of whom the previous operation had been done two years before, and in whom there were abscesses around heavy loops of wire, with resultant sinus tracts If smaller wire had been used, the chances are that the abscesses would not have occurred However, the finer the caliber of the wire, the greater is the chance of cutting through

Whatever suture material is used, the importance of not "cutting on the knot" should be again stressed Too many house men are still being taught to cut on the knot The important experimental work of Price has shown that any suture material, even wire, will become untied if the suture is cut on the knot He found that the suture should be cut so that the ends left are at least 2 mm long

Statistical Data

In the statistical data here furnished, reference is made to the number of actual hernias operated on It is felt that it will only becloud the issue to talk about bilateral or unilateral hernias It is my feeling that there is no more reason for having a recurrence when the patient has two inguinal hernias than when he has only one, if the case is properly managed It is my practice, in operating on a patient with bilateral inguinal hernias, to operate on the worst side first If, after completing the operation on that side, it is felt undesirable for any reason to operate on the second side at the same time, I defer the operation on the second side, no matter how anxious the patient may have been to have both sides operated on at once By following this practice, I believe that as good results can be obtained in patients with bilateral hernias as in those with only single hernias, despite the fact that most recorded statistics are to the contrary The poorer results in operating on bilateral hernias are probably due to poor judgment in routinely doing both sides at once, in spite of the conditions found at time of operation

In the series here reported, there was probably the usual proportion of cases of bilateral hernia The proportion, however, may have been slightly less than the average, owing to the fact that a great many cases were recurrent cases However, in a great many of the cases the recurrence was bilateral

Four hundred thirty-six hernias are reported in this series Of that number, 99 may be considered ordinary run-of-the-mine cases which were easy to cure, provided that a proper and careful operation was done Three hundred thirty-seven of the cases, however, might be considered far from run-of-the-mine in that the hernias were associated with poor tissues, there were large defects, or the hernias were large or recurrent These cases may be divided into the categories shown in the accompanying table ('sliding,' as used in the table, means sliding hernia of the large intestine)

Categories of Hernias

Primary Hernias with Poor Tissues	
Indirect	61
Direct	[illegible]
Saddlebag	36
Scrotal	38
Sliding	20
Scrotal sliding	20
	246
Recurrent Hernias	
Once recurrent (4 scrotal 3 sliding)	49
Twice recurrent (2 scrotal 3 sliding)	31
Thrice recurrent	7
Four times recurrent	3
Seven times recurrent	1
	91

Of the 91 recurrent hernias, 46 were direct, 34 were indirect, and 11 were saddlebag These figures pretty well coincide with reported figures from other authors on the nature of recurrent hernias It was obvious in some of the indirect recurrences that the sac had not been obliterated at all at the first operation, because in several of these cases the sac was of the congenital variety with the testis still in it This is a sad commentary on the operation for hernia as performed by some surgeons Undoubtedly the situation is improving, but there is still room for improvement

Only five cases in this series were strangulated In five cases of huge scrotal sliding hernias it was necessary to cut the oblique muscles in order to reduce the huge mass of intestine through the internal ring This method has been previously described [17] In only four cases was it considered necessary to transect the cord I believe that this is only necessary in those few cases in which there is so much cartilaginous scar tissue due to previous operations that the presence of the cord would be an actual deterrent to a cure of the hernia Ordinarily this is not the case, the cord can be left, and the structures snugly sutured about it at the internal ring

In two cases the bladder was entered In both of these cases there was a sliding hernia of a diverticulum of the bladder, with only the mucosa of the bladder forming the wall of the diverticulum The usual bladder musculature was absent, to warn the surgeon that he was near the bladder These cases have been reported elsewhere [16] In a third case a diverticulum of the bladder was encountered but was recognized before it was entered In the series there were many cases of sliding hernia of the bladder in direct hernias, but these presented no special problem

In a large proportion of the 337 special cases tabulated above, either tantalum gauze or cutis grafts (14 cases) were used as reinforcement materials

Results

Realizing that there is no such thing as a completely satisfactory follow-up system, I have tried to obviate the defects of the periodic follow-up by trying to keep in constant contact with my patients It is my practice to check hernia cases every six months for the first two years and after that once a year as long as the patients are willing to come back Most of them are very glad to come back A great many who live in distant cities come back If they do not, they are at least written to, and a report is obtained from them or from their physicians In spite of this, there are always a certain number of patients who through indifference or change of address are lot sight of Only those who could be followed up are included in this series

There were no deaths in the series, although many of the patients were in the aged group, being in the 70s and 80s (the oldest was 89 years of age) Most of the aged patients had large disabling hernias with poor tissues, and they often had associated debilitating diseases Most of these were operated on under spinal or local anesthesia

In a great many of the recurrent cases, the anatomy had been badly distorted by previous operations, and frequently Poupart's ligament had been cut at one of the previous operations The easiest recurrent hernias to repair are those in which the preceding surgeon did little or nothing at the time of his operation, not even removing the indirect sac Fortunately we are seeing fewer of such cases

There were two recurrences in the patients here reported on Both of these were early cases in which tantalum gauze was used as a reinforcing material before the technique for its use had been well developed One patient was an older man who had a twice recurrent hernia and exceedingly poor tissues A Cooper's ligament repair was done The suture line (conjoined tendon to Cooper's ligament) was reinforced by only a narrow piece of tantalum gauze, just wide enough to cover the suture line Experience soon showed that this was not sufficient (as recurrence was prompt) and that, if tantalum was to be used, the entire area should be covered This patient was reoperated on by me and has now been well for seven years since the second operation

The second recurrence was in a woman with flimsy and frail tissues, in whom the conjoined tendon had been sutured to Poupart's ligament and the suture line reinforced with a narrow piece of tantalum gauze This proved to be as inadvisable as in the case just mentioned This patient was also reoperated on by me and remained well for three years, until she died of hemorrhage from a ruptured esophageal varix, which was due to cirrhosis of the liver

In a third case in which I used a piece of tantalum gauze to cover the Hesselbach triangle area[12] in operating for a recurrent direct hernia, an indirect hernia appeared two years later The direct repair was still strong and was not molested when the indirect hernia was repaired The appearance of the indirect hernia would ordinarily be called a recurrence However, the patient had never had an indirect hernia So, how could it be a recurrence? The possibility must be borne in mind, of course, that at my first operation on this patient I may have missed an indirect hernia that was acutally there at the time, as I had not examined the internal ring through a LaRoque muscle-splitting incision It was this experience that led me to abandon using a small piece of tantalum gauze in inguinal hernia repair and to use the present method (fig 5) of covering the entire hernial area This is essentially the method used by Throckmorton except that I do not turn the edges of the tantalum gauze under and suture only the lower edge to Pouparts ligament, depending upon the aponeurosis of the external oblique to hold the tantalum in place

Of the 436 patients whose cases are here reported, 50 were operated on less than a year before the time of writing There have been no recurrences in them The other 386 cases have been followed from 1 to 22 years While it is true that some hernias do recur after a period of many years, it is my feeling that most recurrences take place within the first six months and nearly all within the first two years Naturally, no one can be absolutely sure that a hernia will not recur as long as the patient is still alive

Of the 386 patients operated on more than a year ago, 45 have been well 1 year or more, 49, 2 years or more, 43, 3 years or more 42, 4 years or more, and 207 have been well from 5 to 22 years

The recurrence rate in this series is 0 46%, if only the two cases of actual recurrence mentioned above are included If the third case, in which an indirect hernia followed two years later after the repair of a direct hernia, is included, the recurrence rate is 0 69% Experience in checking these cases over a number of years makes me believe that, as the years go by, this percentage will not be materially increased This may seem like an unjustifiable statement Yet, it is the firmness of the repair at repeated yearly examination which gives one faith in the methods used It is especially noteworthy how strong the repair feels years afterward in those cases in which tantalum gauze has been used

Conclusions

I am aware of the fact that other surgeons who have used other methods of repair of inguinal hernia have sometimes obtained as good results There are unquestionably many methods that may be used in successful hernia repair The important thing is for the surgeon to realize the importance of exercising infinite care and pains in every single step of the operation, no matter how inconsequential the hernia may seem to be If this is done, success may be attained with many methods, if it is not done, failure is invited with any method

The methods here described are felt to be dependable and have given me a high degree of success in the repair of this widespread and troublesome condition

ORGANIZATION AND POSITION OF MEDICINE TODAY

Gordon F. Harkness, M.D., Davenport, Iowa

• *The primary and absorbing interest of the physician is to give the best he has for the benefit of the sick person. Nevertheless, he must also give thoughtful consideration to the changes in the social fabric and to the philosophy and economics of modern living. Organization is necessary, and the success of a democratic organization depends on a sense of responsibility in its members. They should be aware of the constructive work that is being done. No other group has demonstrated a greater devotion to human welfare or contributed more to science than the medical profession. Its humanitarian and scientific achievements constitute a wonderful heritage, and it is the individual physician's responsibility and duty to help preserve it.*

The American Medical Association is your association. The ramifications of the A. M. A. are many. It should be a sort of guiding light to all of us, remembering that it is only an amalgamation of component parts—first, of the state societies and, then, in turn, of their component parts, the county medical societies. It is to be remembered that each of these units has its inherent rights and responsibilities. No matter to what special field of medicine one may limit himself we are all doctors of medicine and have an individual responsibility relative to measures for the common good, for the benefit of humanity, and for the protection of our professional interests.

The A. M. A., recognizing scientific progress and the consequent development of more specialized fields of medicine, has instituted scientific assemblies of these special groups at its annual meetings. It has also recognized that in its organizational form it the House of Delegates, whose members are chosen by the state organizations, is the final authoritative body. It has gone further and recognized that to be truly democratic it must permit special fields of medicine to have a minority representation and that it must give each scientific section the right to elect one delegate to represent that section. In that capacity I have tried, for a number of years, to represent the Section on Laryngology, Otology and Rhinology to the best of my ability.

The House of Delegates works a good deal like our national Congress. A great mass of resolutions is introduced each session. The resolutions are referred to reference committees, which expedite them and give them thoughtful consideration. Here any member or delegate can appear and offer his arguments for or against any resolution. Then the committee brings its report relative to each resolution to the House of Delegates, which alone has the final authority. Much of a delegate's work is accomplished before the reference committees, though he always retains the right to present his arguments on the floor of the House.

Problems of Delegates

In the beginning some of the section delegates found themselves very much alone, lone mavericks, as it were, though my own state delegates always took me in as one of their own. Several years ago, the section delegates formed an informal, intimate unofficial organization. Two breakfasts are held during each session. It is in no sense a small political block. No votes are ever taken, no minutes are recorded, and no voting obligations are asked of each other. But it does give a section delegate an opportunity to explain any problems he might have and to obtain the aid of sympathetic fellow delegates who might be interested in helping to promote his ideas. It takes time for a delegate to familiarize himself with the procedures and to learn how to conduct himself most effectively.

I would like to mention just one problem, the most important and difficult one that I have encountered since I have represented this section in the House of Delegates. It was difficult primarily because, in representing the section and its members wishes I found myself in opposition to the views of the Board of Trustees. Let me emphasize, this is no criticism of the Board. No one holds it in greater respect, as a body, than I do. Its members are earnest gentlemen, giving of their time and effort for the benefit of the medical profession. As various problems arise, these men describe the picture as they see it.

This problem concerned the status of the dental-oral surgeon on the hospital staff and the limitations of his field. This section and others felt that there was a deliberate attempt by this group of the dental profession to invade the practice of medicine and surgery. This was unfortunate, because the medical and dental professions should be working together as a team. All that was proposed from the House of Delegates was a statement of approved policy without in any way invading the inherent rights of local organizations. It took three years to get this statement established as originally requested. This was accomplished with each group giving the other credit for sincerity of purpose. Although it may have appeared that I carried on a lone controversy, I had valuable assistance indirectly from individuals and from some groups.

The incident is closed, and an account of it might be misinterpreted if published, but I do think that members of the A. M. A. are entitled to know something of the trials and tribulations of a delegate and to be given an epitome of the controversy. The House of Delegates affirmed my request in 1953 and reaffirmed it in 1955. I sincerely hope that this particular controversy is now ended.

Address of honorary chairman, read before the Section on Laryngology, Otology and Rhinology at the 105th Annual Meeting of the American Medical Association, Chicago, June 12 1956.

Medicine Today

Some of my thoughts relative to our profession as of today are based on the following premises

1 Scientific medicine stands in the foreground of the scientific achievements of the past 50 years Its position cannot be disputed

2 The younger men in our profession have the same ideals that prompted those of us who are now in the twilight zone of professional life when we subscribed to the Hippocratic Oath

3 No other group has demonstrated a greater devotion to human welfare More harm is done, in influencing public attitude, by one doctor who strays from the path of rectitude than can be compensated for by 100 altruistic professional or charitable services

4 The accomplishments of medicine had their birth and development during an era of individual freedom and acceptance of individual responsibility A similar acceptance of responsibility by the American people has brought our country to its present preeminent position

5 We have in our profession a wonderful heritage, and it is our individual responsibility and duty to help preserve

Socialized Medicine—The socialist trends that have become a part of our lives in the last 30 years, trends that have become a part of governmental assumption, are disturbing It is axiomatic that the more functions the government assumes the less individual freedom you have When such trends become a part of the social fabric, their rescindment is far more difficult to attain than the original accomplishment Why have these things happened? Is it due to a changing philosophy of life? Is it due to a changing economic phase of life or to a political promise of a mass utopia? I do not pretend to have the specific answers Call it a combination of factors, but I feel that complacency on the part of individual members of our profession is our greatest weakness In what way are we to blame? Have we failed individually? A little self-analysis is always good for any individual or group

In approaching this problem, every doctor, no matter how limited his field may be, must realize that ultimately government supervision of caring for the ill will be decided not by the medical profession but by the public Here the political factor plays a big role This brings us to a realization that it is our responsibility to convince the public that we can do a better job medically and economically and voluntarily than can any government bureau

Public Relations—Today it is popular to turn to our so-called public relations programs I never heard of public relations for the medical profession when I started to practice medicine The doctor was a very highly respected man in his community Let us bear in mind that the keystone of good public relations is the attitude of the individual doctor toward his individual patient, rich or poor Yet the doctor, individually, is important in his influence beyond his own small sphere So, acknowledging this importance, it becomes necessary to turn to organized medicine to facilitate mass education Recent surveys have shown that lay individuals overwhelmingly still think well of their own doctors, but many are in doubt concerning the medical profession as a whole Why do they have such a feeling? It is our responsibility to discover the reasons and to correct them

Organized medicine has established, through many state organizations, so-called grievance committees and has advertised them to the public I commend this, though I would prefer use of the word 'adjustment" rather than 'grievance " While the word 'grievance' crystallizes the committees' purpose in the public mind, at the same time it carries with it the idea that there must be something wrong if the medical profession feels the necessity of establishing such committees Since most of these grievances are economic, I would suggest that, when information about the setting up of these liaison committees is disseminated, a statistical report be included showing what a small factor these grievances play in economic and professional relations Let us be positive in our public relations and not engage in a defensive campaign It is deplorable that there are articles in lay publications, some of them by physicians, that emphasize the derelictions of a few and imply that if a doctor belongs to certain organizations he is infallible but that tend to leave doubt in the reader's mind as to those doctors not associated with these organizations

Can it be that the cost of medical care is a predominating factor in affecting public attitude? Surveys do not support this contention, particularly as to the individual's feelings toward his own physician (Few people realize that with the advances in scientific medicine the actual over-all cost of good medical care, preventive and therapeutic, is less per capita than years ago Many diseases are now practically nonexistent, and the period of illness has been markedly reduced in many other diseases) I think the burden of medical care has a more fundamental basis, economically speaking

It is to be remembered that there are four fundamental essentials in living They are food, housing clothing, and medical care The first three factors are constant and can be provided for by the employed individual through budgeting according to his income, but the fourth, medical care, is not a constant factor The time of its need is unpredictable There may be long intervals when it does not enter the picture and then it may strike with overwhelming force and almost cause a financial disaster The only answer for this is budgeting regularly through insurance Let me add that the so-called social security program, now a part of our government fabric, makes no claim to being an actuarily sound insurance program It is in no way a protection from the cost of illness In fact, it is only an acceptance by government of certain required payments from its citizens, without reserve funds being set aside on an actuarial basis, and a promise by government to meet specified obligations by future taxation if current funds do not meet them

The only way left for the individual to meet these unexpected costs in this fourth essential factor of living is through budgeting for it by means of insurance We have good commercial companies offering this protection on an indemnity basis We have the Blue Shield programs going even farther and offering full service, within certain family income limits, through the cooperation of the medical profession These programs are the profession's answer to the socialization of medical care, but we have to demonstrate to the general public that we can provide this protection with better care than can be done through government domination Government domination has shown its inadequacies in other countries

Comment

I fully realize that this is rather an unusual theme to present before a scientific section My only reason for presenting it is a deep personal conviction that the greatest danger to our heritage is our own individual complacency I know of no group of more individualistic men and women than those in the field of medicine Our primary and absorbing interest is to give the best we have for the benefit of the sick individual We cannot retire to the cloisters of scientific medicine It behooves each one of us to give thoughtful consideration to the changes in our social fabric and to the philosophy and economics of modern living We must realize that as individuals our influence is limited Today, as never before, organized efforts have become a necessity No matter how limited one's field in medicine may be, each one of us is a unit in the entire field of medicine

Organization in medicine crystallizes itself in the A M A The responsibilities of the A M A have multiplied many times, yet, it remains a democratic organization through its component units I find that there are far too many in our own ranks who give little thought to and have little knowledge of the constructive work that is being done Your association is the only organization that can speak for all of us, not as a dictatorship or an oligarchy, but as a democratic organization But, it is to be remembered that the success of any democracy depends upon the assumption of individual thoughtful consideration and responsibility by its members

We are fortunate in having men who give their time, often with personal sacrifice, in an endeavor to solve our problems relative to human welfare Destructive criticism accomplishes nothing, but constructive criticism should always be welcome The latter often has its birth in the mind of an individual who after careful thought realizes that organizational efforts are a necessity Any organization is only as strong as its component parts, and the ultimate units are you and me

CLINICAL NOTES

SUBCUTANEOUS UROGRAPHY IN INFANTS

Bernard S Epstein, M D, New Hyde Park, N Y

Radiologic examination of the urinary tract in infants is frequently a trying experience because of the technical aspects of venipuncture Urography may be accomplished by the intramuscular injection of a 15% to a 35% solution of iodopyracet (Diodrast) compound,[1] but in my experience this has been painful to the infant The addition of hyaluronidase for the subcutaneous or the intramuscular administration of iodopyracet has been recommended by Olsson and Lofgren[2] and Astley,[3] while Fainsinger[4] and Begley[5] prefer the intramuscular use of the contrast medium after the site of injection has previously been prepared by the administration of hyaluronidase

Subcutaneous urography was used by Nesbit and Douglas[6] in 31 patients of various ages They used 20 cc of a 35% solution of iodopyracet diluted to 100 cc with isotonic sodium chloride solution, half of the mixture was injected over the angle of each scapula Others who recommended the subcutaneous route were Higgins and Shively[7] and Mullen[8] One 2-year-old child, in whom a 50% solution of diatrizoate (Hypaque) sodium was administered intramuscularly, with satisfactory results and with no ill-effects, has been mentioned by Mahoney[9]

For many years I have routinely employed subcutaneous pyelography in infants, administering 15 cc of iodopyracet compound diluted with an equal amount of sterile isotonic sodium chloride solution or distilled water and injecting half of the total mixture at a site adjacent to the angles of the scapulas or to the lateral aspect of each thigh I continued to use this method with a 50% solution of diatrizoate, and the present report concerns such subcutaneous pyelography in 25 patients, all of whom were infants less than 16 months of age Ten were less than 3 months old, including 4 newborn infants, three infants were between 3 and 6 months old, six were from 6 to 12 months old, and four were between 12 and 16 months of age Two patients had 2 examinations each, so that the total number of studies was 27

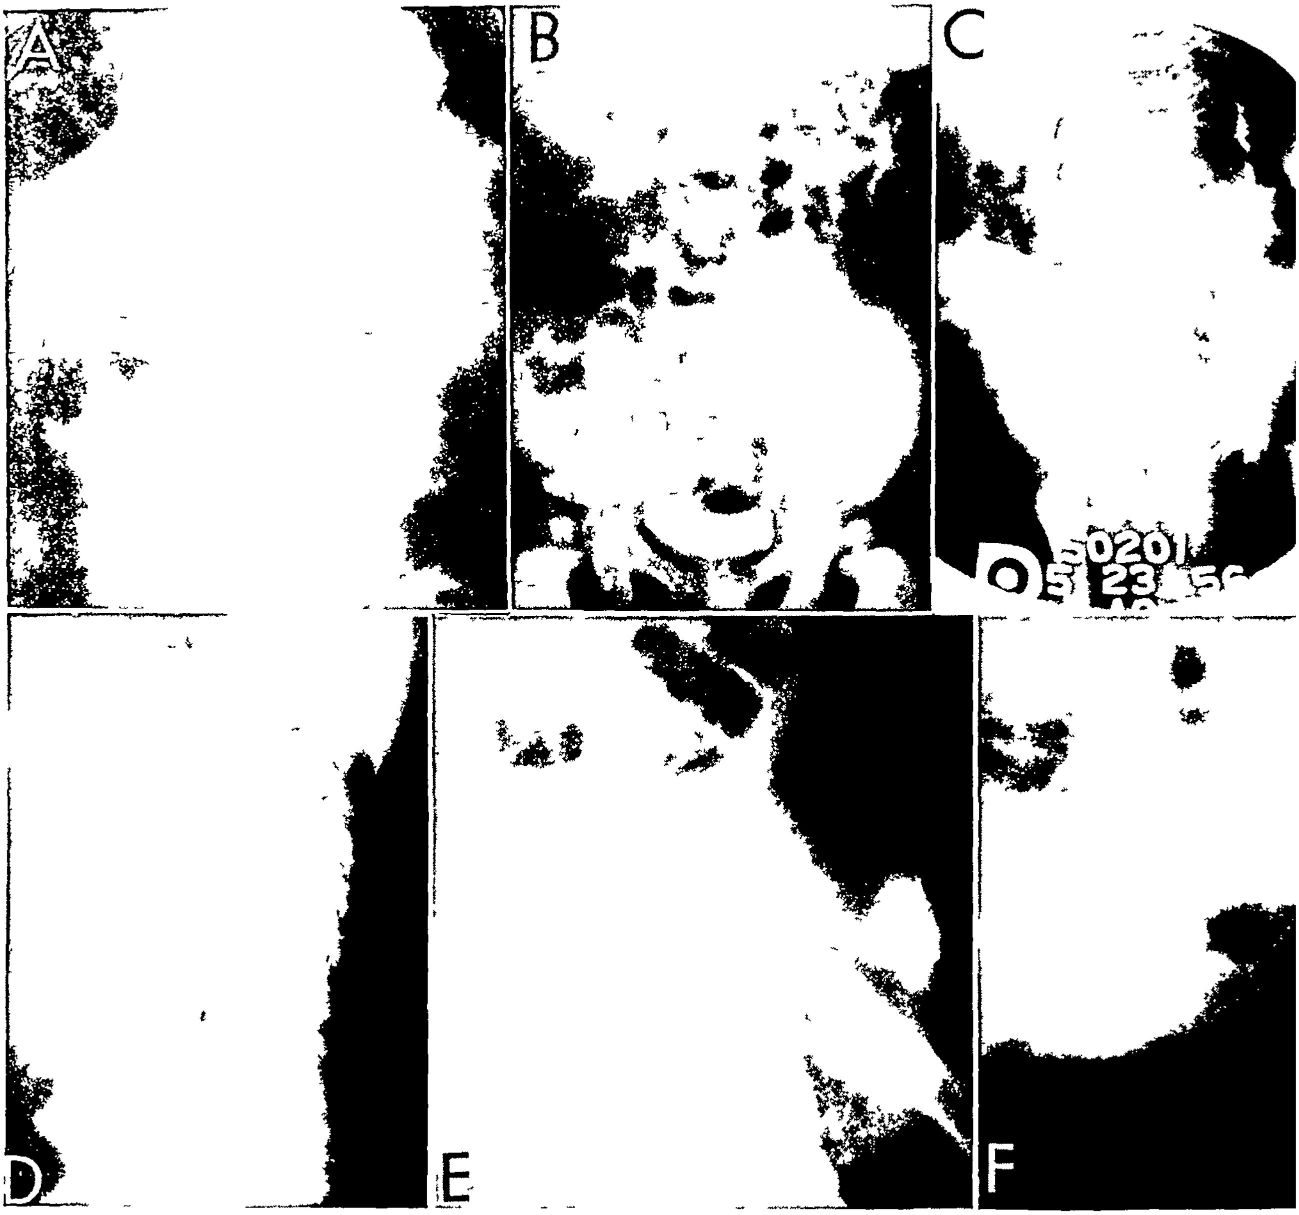
Roentgenograms were taken at intervals of from 10 to 20 minutes for at least one hour The concentration of the contrast medium in the kidney pelves and the bladder usually was best after about 15 to 30 minutes The excretion of the subcutaneous deposits of diluted diatrizoate was slow, as evidenced by the amount of radiopaque material remaining in the subcutaneous tissues during the examination The injections were accomplished rapidly and were relatively painless except for the insertion of the needle and the discomfort of distending the subcutaneous tissues The patients were

---

From the Department of Radiology, the Long Island Jewish Hospital permitted to lie on their backs immediately after the injections and absorption was almost complete in about two hours

An advantage of the subcutaneous route is the relatively slow absorption, which makes it possible to obtain roentgenograms over a relatively long time This permits time to view the wet films and to repeat studies when necessary for technical reasons Another advantage over the intramuscular route, as has already been mentioned, is the lack of undue pain for the child The ever-present possibility of formation of a hematoma upon intramuscular injection of any agent is, course, not to be overlooked It is for these reasons t I prefer the subcutaneous route of adminis

There were two patients in the present group whom there was poor visualization One had a co genital anomaly of the kidneys with a megaureter T second was a 15-day-old infant, in whom considera gaseous distention of the intestine obscured the kidn shadows Nevertheless, the films were sufficiently di nostic for it to be ascertained that the urinary tr was normal



A subcutaneous pyelogram in 7-month-old infant five minutes after injection of 15 cc of 25% diatrizoate sodium adjacent to e scapula None of the contrast medium is seen in the urinary tract *B*, same patient as in part *A*, 65 minutes after injection of c trast medium Kidneys and bladder are well demonstrated Almost all contrast medium has been absorbed from intrascapular a *C* subcutaneous pyelogram in 6-week-old male infant, made 40 minutes after patient had ingested 25 cc of carbonated bever Kidney pelves and calices and bladder are well opacified *D*, same patient as in part *C* Lateral roentgenogram after 50 minu Considerable amount of contrast medium is still seen in subcutaneous tissues overlying back Opacification of kidneys, ureters, bladder is adequate for their demonstration in lateral view *E*, voiding cystogram of 7-month-old baby with hypospadias Urethr well outlined Deformity of the distal urethra can be seen *F*, oblique cystogram of newborn infant with myelomeningocele Urac is filled from its bladder end about midway to umbilicus

Normal pyelograms were obtained in 11 patients, and a wide variety of pathological conditions was fied in the remaining patients (see figure) One had a hypospadias, and a voiding cystogram gave an excellent portrayal of the urethra (see figure, *E*) Another child with a myelomeningocele had a urachus patent up to a point about 2 cm from the umbilicus that could be nicely identified on lateral views (see figure, *F*) There were two patients with neuroblastomas, urethral displacement was demonstrated in one at the level of the lower part of the lumbar spine, and downward displacement of the right kidney was seen in the other An ectopic kidney in another child was confirmed by retrograde study, while still another child had a double kidney and ureter Marked hydronephrosis due to congenital ureterocele impinging on the vesical neck was present in one child

Summary

Subcutaneous urography with a 50% solution of diatrizoate (Hypaque) sodium diluted to 25% is advantageous in infants The usual dose for children up to about 16 months is 15 cc diluted to 30 cc with 15 cc injected parascapularly on either side The injections may be accomplished rapidly and with little discomfort to the patient Twenty-three of 25 films obtained were satisfactory, while the remaining 2 were of sufficient clarity to permit a diagnosis of a normal urinary tract

270 05 76th Ave

The diatrizoate sodium used in this study was supplied as Hypaque sodium by the Medical Research Department of Winthrop Laboratories, New York

ECCHYMOTIC SKIN LESIONS IN PATIENTS RECEIVING PREDNISONE

Charles W Denko, M D
and
Leslie R Schroeder, M D, Chicago

Undesirable effects of varying severity have been noted in patients being treated with steroids that produce clinical effects similar to those of cortisone Few reports deal extensively with the occurrence of purpura, spontaneous ecchymosis, or easy bruising after the administration of these hormones Such skin lesions were noted in 18 to 34% of patients with rheumatoid arthritis receiving prednisone and prednisolone[1] Purpura was also reported as an untoward effect in arthritic patients maintained in an induced hyperadrenal state[2] When patients received cortisone, hydrocortisone, or adrenocorticotropin, the incidence of such skin disturbances was placed at 2 to 5%[3] No blood or coagulation studies to explain these phenomena were reported An opportunity to study this disorder in some detail was presented during the past year, when we observed a similar incidence (20%) of purpuric lesions in a group of 75 patients treated with prednisone for a variety of rheumatological disorders This paper presents an investigation of the coagulation mechanism in evaluating this bleeding tendency noted in patients receiving prednisone

Materials and Methods

All patients exhibiting purpuric lesions were women Each may be regarded as her own control, since she was observed for many months prior to prednisone therapy during which time no abnormal bleeding occurred Only two patients had histories of purpura one (case 10) while receiving cortisone 3 years previously, and one (case 7) while receiving an experimental drug 15 years previously All had fair to excellent relief of their rheumatological distress on receiving prednisone initially

The physical findings in these patients before treatment were those usually observed in patients with various arthritides Routine blood and laboratory studies included repeated determinations of leukocyte count, hemoglobin level, hematocrit, erythrocyte sedimentation rate, differential count, and serum albumin globulin, and C-reactive protein levels In general, the patients with rheumatoid arthritis and systemic lupus erythematosus had laboratory findings consistent with those usually noted in these disorders The changes in blood studies noted after treatment with prednisone were those usually observed after use of this drug, e g, a decrease in serum C-reactive protein level

---

From the Department of Medicine, University of Chicago Dr Denko is now with the Rackham Arthritis Research Unit, University of Michigan Medical School, Ann Arbor, Mich

Patients also demonstrated reduced inflammation in the involved joints, with a decrease in swelling, redness, and heat and with an increase in mobility

The following studies on the coagulation mechanism were done in nine patients Rumpel-Leede test, platelet count, prothrombin time, prothrombin consumption time, plasma recalcification time, clot retraction, bleeding time, clotting time in glass and in siliconed glass tubes, and fibrinogen level The methods used were as follows Rumpel-Leede test by sphygmomanometer cuff applied to arm for five minutes at a pressure between systolic and diastolic, usually 90 to 100 mm Hg, and determination of platelets by direct count[4] of prothrombin time by a modification of the one-stage Quick method using Simplastin[5], of prothrombin consumption by the one-stage method[6], of plasma recalcification time by the method of Rosenthal[7], of bleeding time by Duke's method[8], and of fibrinogen levels by the Ratnoff technique[9] Determination of clotting time in glass was done by the three-tube modification of the Lee-White method

Comment

A summary of the studies on coagulation is presented in the table A positive Rumpel-Leede test occurring in all patients indicated consistently some disturbance of normal capillary function, a decrease in capillary resistance The clinical findings of ecchymotic skin lesions in patients with hypercortisonism probably reflect this decreased capillary resistance Interestingly, capillary resistance has been reported to increase after administration of cortisone or corticotropin in patients with rheumatoid arthritis[10] Furthermore, cortisone and prednisone are widely used t control ecchymosis and spontaneous petechiae i hemorrhagic diseases

The skin areas involved, in the order of frequenc of involvement, include upper and lower legs an arms, thorax, and breasts Ecchymoses have bee observed as early as 17 days after the initiation o prednisone therapy and as late as seven months afte beginning treatment This bleeding tendency has occurred in patients receiving as little as 5 mg of prednisone per day Prednisone alone or prednisone plu acetylsalicylic acid comprised the usual therapeut program Most patients had been observed previousl for many months while receiving acetylsalicylic aci during which time they had developed no ecchymotic lesions In two patients (cases 4 and 9) menstrual flow was increased in intensity and duration

Ordinarily the skin lesions were irregular in size, one square millimeter to several square centimeters in area The bluish-purple color faded gradually after a few weeks of reduced prednisone dosage The Rumpel-Leede test remained positive for four to eight weeks after prednisone therapy was discontinued In two patients (cases 4 and 9) focal areas of tenderness, 1 to 2 cm in diameter, developed with a firm nodule, 1 to 2 mm in diameter, centrally placed These areas became ecchymotic one to two days after appearance The widest involvement, showers of petechiae, occurred in the patient (case 14) receiving the highest dose of prednisone After this patient died of rheumatic heart disease, the skin lesions were examined microscopically, but no evidence of embolic phenomena was found

Ascorbic acid, 50 mg given twice daily, produced a slight improvement in the skin lesions in some patients Discontinuance of prednisone therapy produced a complete clearing of the skin in several patients For clinical reasons prednisone therapy was continued in other patients for periods ranging to nine months, without any significant worsening of side-effects

The alteration in platelet or capillary physiology produced by prednisone in these patients is difficult to explain Speculation leads one to consider some metabolic derangement involving ascorbic acid, since ascorbic acid appears to decrease somewhat the incidence of spontaneous ecchymosis Moderate declines in fibrinogen level in two patients (cases 6 and 9) indicate some interference in fibrinogen synthesis, an effect of steroids noted previously[11] Perhaps some property of the platelets or capillaries not studied in these tests may be altered Whatever the derangement in the capillaries or platelets induced by these steroids, it is apparently more characteristic of prednisone than of the other compounds

Summary

The occurrence of purpura, ecchymotic skin lesions, and easy bruising was noted in 20% of a group of 75 patients receiving prednisone for a variety of rheumatological disorders In all of these patients a positive Rumpel-Leede test was found Platelet and coagulation mechanism studies revealed the following normal studies prothrombin time, prothrombin consumption, clot retraction, platelets, bleeding time, and clotting time Moderate declines in fibrinogen levels occurred in two patients Some benefit from treatment programs was noted

Addendum

Ascorbic acid, 100 mg given twice daily, has been found recently to be more effective in improving skin lesions

Hepatolenticular Degeneration —An increased concentration of copper in both the liver and brain of patients dying of Wilson's disease (hepatolenticular degeneration, H L D) was noted by Haurowitz, Luthy and Glazebrook These observations, all made on single cases, were confirmed and extended by Cummings who reported a series of three patients who died of H L D It is now known that, in addition to the excess copper in the tissues, there is an increased excretion of copper in the urine, a low plasma copper concentration and a very low level of ceruloplasmin, the copper-binding or globulin This last is believed to be the primary biochemical defect in Wilson's disease The removal of excess copper from patients with H L D by the parenteral use of 2, 3-dimercaptopropanol (BAL), $\mathrm{CH_2,SH,CHSH,CH_2OH}$ was first reported by Mandlebrote and Thompson and has been confirmed by many subsequent workers Given in repeated courses and over long periods of time BAL may lead to marked clinical improvement although in the more acute forms of the disease the results are less satisfactory Intravenous versene and amino acids have also been shown to increase the copper excretion, as well as high protein diets and cortisone Absorption of copper from the intestine can be reduced by the oral administration of potassium sulphide or carbo-resin A new form of oral treatment with dimethyl cysteine (penicillamine) is described Given in doses varying from 0 5 to 1 5 gm daily to six patients with Wilson's disease, it provoked a very large increase in the urine excretion of copper, in five patients it proved more active than BAL in this respect —J M Walshe, Penicillamine, a New Oral Therapy for Wilson's Disease, *The American Journal of Medicine,* October, 1956

Patients also demonstrated reduced inflammation in the involved joints, with a decrease in swelling, redness, and heat and with an increase in mobility

The following studies on the coagulation mechanism were done in nine patients Rumpel-Leede test, platelet count, prothrombin time, prothrombin consumption time, plasma recalcification time, clot retraction, bleeding time, clotting time in glass and in siliconed glass tubes, and fibrinogen level The methods used were as follows Rumpel-Leede test by sphygmomanometer cuff applied to arm for five minutes at a pressure between systolic and diastolic, usually 90 to 100 mm Hg, and determination of platelets by direct count [4], of prothrombin time by a modification of the one-stage Quick method using Simplastin [5], of prothrombin consumption by the one-stage method [6], of plasma recalcification time by the method of Rosenthal [7], of bleeding time by Duke's method [8], and of fibrinogen levels by the Ratnoff technique [9] Determination of clotting time in glass was done by the three-tube modification of the Lee-White method

COUNCIL ON DRUGS

Formerly the Council on Pharmacy and Chemistry

Report to the Council

The Council has authorized publication of the following report Nonproprietary terminology is used for all drugs that are mentioned, when such terminology is not considered to be generally well known, its initial appearance is supplemented by parenthetic insertion of names known to be applied to commercial preparations

H D Kautz, M D, *Secretary*

MIXTURES OF ANTIBIOTICS

Harry F Dowling, M D, Chicago

The recent marketing of several novel mixtures of tibiotics has revived interest in the value of com- tions of antibiotics Various claims have been de for the superiority of a mixture of two antibiot- cs over either of the drugs used alone It is claimed that mixtures of antibiotics should be used for the following reasons (1) to produce a better therapeutic result than can be achieved by maximal dosage of either antibiotic alone (synergism), (2) to achieve a therapeutic result with nontoxic doses of two antibiotics that would require a toxic dose of either antibiotic alone, (3) to prevent or delay the appearance of resistant strains of infecting organisms, (4) to treat mixed infections in which no single antibiotic is effective against all of the organisms present, and (5) to treat seriously ill patients before a bacteriological diagnosis is made These claims will be considered in the order in which they are listed

Synergism and Antagonism

The problem of synergism was ably reviewed by Jawetz and Gunnison [1] in a report to the Council on Pharmacy and Chemistry in 1952, and more extensively elsewhere [2] Other reviews of this subject were written by Garrod [3] and Dowling, Lepper, and Jackson [4] In the present report the status of combined antibiotic therapy at the time the previous reports were written will be summarized Recent studies will then be added and the total picture evaluated

In experiments in vitro and in animals, when the effect of two drugs acting simultaneously on a microbial population is compared with the effect of either drug alone, the result may be synergism, simple addition, indifference (no increased or decreased action), or antagonism (an effect that is less than that achieved with the most effective of the two drugs acting alone) The term synergism has been defined differently by different investigators In general, it is agreed that synergism means that the antimicrobial effect obtained from the use of a combination is greater than the sum of the effects of each of the component agents acting alone The methods used to determine synergism differ greatly, however The method most commonly
used for determining in vitro whether a gi
nation will produce synergism, antagonism,
ence is the observation of the amount of
and of the drug combination necessary t
growth in the test tube or to delay growth
period of time The results are expressed as
weight of drug necessary to suppress gr
delay the appearance of growth Synergi
claimed if inhibition of growth is achie
than half the minimal inhibitory concentr
drug, plus half or less than half the minim
concentration of the second drug Biolo
ments cannot be done accurately enou
anything less than a fourfold difference
however, this method of reasoning is fa
cause there is no evidence that half the
duces half the activity of the full amount
In fact, experimental evidence shows that
is true, namely, that the weight and
activity do not have a linear relationship

An in vitro test giving results that most
lel those observed in animals and in p
subculturing of micro-organisms at inte
posure to the drugs and combinations te
determines the rate and completeness o

kill bacteria in the early hours of the
compared with the rate of killing pro
individual antibiotics during the same
as an index of synergism, indifference, o

Studies in animals have added anot
dimension to the observations As the
the two antibiotics in a given mixture h
ied, either synergism, indifference, or
been demonstrated The evidence fro
animal experiments was summarized
Gunnison [1] by listing antibiotics in two
1(primarily bactericidal) containing p
tomycin, bacitracin, and neomycin (M
guent, Neomycin), and group 2 (prim
static) containing chlortetracycline
oxytetracycline (Terramycin), tetrac
cin, Panmycin, Polycycline, Steclin,
cyn), chloramphenicol (Chloromyceti
(Erythrocin, Ilotycin), and carbom
cin) [5]

From the University of Illinois Research and Educational Hospitals and the Department of Medicine, University of Illinois

Mixtures in vitro of members of group 1 frequently show synergism, sometimes indifference, never antagonism Members of group 2 are neither synergistic nor antagonistic to each other, but simple additive effects are often observed In other words the same effect is obtained by increasing the dose of a single antibiotic as by adding an equivalent amount of another antibiotic in the group When an antibiotic from group 1 is used with an antibiotic from group 2, the effect may be synergism, indifference or antagonism Which of these will occur depends upon such complex factors as the relative amounts of the two antibiotics used in the combination and the susceptibility or resistance of the micro organism to the individual antibiotic In no case is it possible to predict whether synergism or antagonism will occur with a given drug combination This can be determined only by actual experiment with a specific drug combination acting on a particular strain of the organism Even when a particular strain is used, the results may vary, depending upon the relative proportions of drugs used

Although there may be exceptions to these generalizations, they agree remarkably well with the results of most laboratory investigations How well does clinical experience correlate with this classification and the experiments upon which it is based? In the few, well-controlled clinical studies, the results have been similar to those obtained in animal experiments and in vitro experiments in which the rate of bacterial killing was used as a criterion Correlation has not been as good between human infections and tests that show inhibition of growth in tubes containing varying proportions of two antibiotics Several newer tests have been devised to show synergism or antagonism in vitro, but no reports of parallel studies of human infection are available Consequently these tests cannot be evaluated at the present time

For clinical purposes, synergism means a therapeutic effect obtained with two or more drugs that could not be obtained with either drug alone in full therapeutic doses, or a lower case-fatality rate in a group of cases when two or more antibiotics are used than when either drug is used alone On the basis of these criteria, it is now universally accepted that synergism has been demonstrated in enterococcic endocarditis with the use of a combination of penicillin and streptomycin, in brucellosis when streptomycin has been administered with one of the tetracyclines or with chloramphenicol, and in certain cases of micrococcic (staphylococcic) endocarditis when a combination of penicillin and chlortetracycline, or streptomycin and oxytetracycline, has been used Reports of several cases of endocarditis have been published as instances of the effective use of other combinations of antibiotics These include administration of penicillin and chloramphenicol in endocarditis caused by Streptococcus viridans [6], oxytetracycline and streptomycin in endocarditis due to Hemophilus organisms [7], erythromycin and streptomycin in endocarditis caused by Micrococcus pyogenes var aureus and by streptococci [8], erythromycin, chlortetracycline, and streptomycin in endocarditis produced by enterococcus [9], and penicillin and bacitracin in endocarditis caused by a diphtheroid [10] Although synergism may have existed in these cases, it was reasonably well proved in two cases only One of Jones and Yow's [8] patients with micrococcic endocarditis was first given erythromycin alone, which was merely suppressive, later a combination of streptomycin and erythromycin was given, which proved curative Since streptomycin alone is rarely curative in micrococcic endocarditis, it is likely that the combination brought about cure when neither drug alone would have done so The patient with endocarditis caused by a diphtheroid bacillus was given penicillin, with resulting suppression of the infection, and recovered after receiving penicillin and bacitracin [10] Since the infecting organism was resistant to bacitracin in vitro, it is unlikely that bacitracin alone would have brought about recovery

A number of investigators have shown that, in endocarditis caused by streptococci that are sensitive to penicillin, combined penicillin and streptomycin therapy for 10 days to 2 weeks is at least as effective as the more prolonged therapy with penicillin alone Some evidence is even available that the case-fatality rate is lower and the relapses are less frequent when the short-term combined therapy is used

Reports have appeared in which claims were made that certain of the newer antibiotics showed synergism when combined with another antibiotic These findings have been confined to in vitro and animal studies, and even these studies are open to different interpretations English and his associates [11] reported on the combined action of oleandomycin (Matromycin) and tetracycline in the proportion 1 2 In vitro studies on the micro-organisms reported showed 'enhanced activity' of the combination, which varied from less than twice that of the sum of the activities of the individual antibiotics to sixfold (in one case twentyfold) the activities of the individual antibiotics A fourfold or greater difference was observed in only 7 of 28 strains No statement was made as to how many strains were examined that did not show such 'synergism'

Three strains of M pyogenes var aureus and one of Streptococcus pyogenes were studied in mice A statistically significant enhancement of therapeutic effect by the combination was observed, as compared with the sum of the effects of the individual drugs This evidence is suggestive enough to warrant further investigation with a number of strains from different human infections and with varying dosage ranges It must be emphasized, however, that synergism in animals, even if established unequivocally does not necessarily mean that synergism will be observed in human infections Furthermore, dosage proportions that show synergism in animals may not be the same as those that show synergism in human infections In fact, they may show indifference or even antagonism when used in humans Finally, the only valid proof of clinical synergism is the unequivocal demonstration by means of adequately controlled studies that superior results are obtained in human infections when the two drugs are used together than when each drug is used singly

Another study [12] reports in vitro and animal investigations on the combined action of oleandomycin and penicillin Although synergistic action was observed with certain organisms and in certain proportions, antagonistic action was apparent when other propor-

Report to the Council

The Council has authorized publication of the following report. Nonproprietary terminology is used for all drugs that are mentioned; when such terminology is not considered to be generally well known, its initial appearance is supplemented by parenthetic insertion of names known to be applied to commercial preparations.

H. D. Kautz, M.D., *Secretary*

MIXTURES OF ANTIBIOTICS

Harry F. Dowling, M.D., Chicago

The recent marketing of several novel mixtures of antibiotics has revived interest in the value of combinations of antibiotics. Various claims have been made for the superiority of a mixture of two antibiotics over either of the drugs used alone. It is claimed that mixtures of antibiotics should be used for the following reasons: (1) to produce a better therapeutic result than can be achieved by maximal dosage of either antibiotic alone (synergism), (2) to achieve a therapeutic result with nontoxic doses of two antibiotics that would require a toxic dose of either antibiotic alone, (3) to prevent or delay the appearance of resistant strains of infecting organisms, (4) to treat mixed infections in which no single antibiotic is effective against all of the organisms present, and (5) to treat seriously ill patients before a bacteriological diagnosis is made. These claims will be considered in the order in which they are listed.

Synergism and Antagonism

The problem of synergism was ably reviewed by Jawetz and Gunnison[1] in a report to the Council on Pharmacy and Chemistry in 1952, and more extensively elsewhere.[2] Other reviews of this subject were written by Garrod[3] and Dowling, Lepper, and Jackson.[4] In the present report the status of combined antibiotic therapy at the time the previous reports were written will be summarized. Recent studies will then be added and the total picture evaluated.

In experiments in vitro and in animals, when the effect of two drugs acting simultaneously on a microbial population is compared with the effect of either drug alone, the result may be synergism, simple addition, indifference (no increased or decreased action), or antagonism (an effect that is less than that achieved with the most effective of the two drugs acting alone). The term synergism has been defined differently by different investigators. In general, it is agreed that synergism means that the antimicrobial effect obtained from the use of a combination is greater than the sum of the effects of each of the component agents acting alone. The methods used to determine synergism differ greatly, however. The method most commonly used for determining in vitro whether a given combination will produce synergism, antagonism, or indifference is the observation of the amount of each drug and of the drug combination necessary to suppress growth in the test tube or to delay growth for a fixed period of time. The results are expressed as a minimal weight of drug necessary to suppress growth or to delay the appearance of growth. Synergism is then claimed if inhibition of growth is achieved by less than half the minimal inhibitory concentration of one drug, plus half or less than half the minimal inhibitory concentration of the second drug. Biological experiments cannot be done accurately enough to make anything less than a fourfold difference significant; however, this method of reasoning is fallacious because there is no evidence that half the weight produces half the activity of the full amount of the drug. In fact, experimental evidence shows that the opposite is true, namely, that the weight and antibacterial activity do not have a linear relationship.

An in vitro test giving results that most closely parallel those observed in animals and in patients is the subculturing of micro-organisms at intervals after exposure to the drugs and combinations tested. This test determines the rate and completeness of killing. The rapidity with which a combination of antibiotics will kill bacteria in the early hours of the experiment, as compared with the rate of killing produced by the individual antibiotics during the same period, is used as an index of synergism, indifference, or antagonism.

Studies in animals have added another important dimension to the observations. As the proportions of the two antibiotics in a given mixture have been varied, either synergism, indifference, or antagonism has been demonstrated. The evidence from in vitro and animal experiments was summarized by Jawetz and Gunnison[1] by listing antibiotics in two groups: group 1 (primarily bactericidal) containing penicillin, streptomycin, bacitracin, and neomycin (Mycifradin, Myciguent, Neomycin), and group 2 (primarily bacteriostatic) containing chlortetracycline (Aureomycin), oxytetracycline (Terramycin), tetracycline (Achromycin, Panmycin, Polycycline, Steclin, Tetrabon, Tetracyn), chloramphenicol (Chloromycetin), erythromycin (Erythrocin, Ilotycin), and carbomycin (Magnamycin).[5]

From the University of Illinois Research and Educational Hospitals and the Department of Medicine, University of Illinois.

Mixtures in vitro of members of group 1 frequently show synergism *sometimes indifference never antagonism*. Members of group 2 are neither synergistic nor antagonistic to each other but simple additive effects are often observed. In other words the same effect is obtained by increasing the dose of a single antibiotic as by adding an equivalent amount of another antibiotic in the group. When an antibiotic from group 1 is used with an antibiotic from group 2 the effect may be synergism indifference or antagonism. Which of these will occur depends upon such complex factors as the relative amounts of the two antibiotics used in the combination and the susceptibility or resistance of the micro organism to the individual antibiotic. In no case is it possible to predict whether synergism or antagonism will occur with a given drug combination. This can be determined only by actual experiment with a specific drug combination acting on a particular strain of the organism. Even when a particular strain is used, the results may vary depending upon the relative proportions of drugs used.

Although there may be exceptions to these generalizations, they agree remarkably well with the results of most laboratory investigations. How well does clinical experience correlate with this classification and the experiments upon which it is based? In the few, well controlled clinical studies the results have been similar to those obtained in animal experiments and in vitro experiments in which the rate of bacterial killing was used as a criterion. Correlation has not been as good between human infections and tests that show inhibition of growth in tubes containing varying proportions of two antibiotics. Several newer tests have been devised to show synergism or antagonism in vitro but no reports of parallel studies of human infection are available. Consequently these tests cannot be evaluated at the present time.

For clinical purposes synergism means a therapeutic effect obtained with two or more drugs that could not *be obt*ained with either drug alone in full therapeutic doses or a lower case fatality rate in a group of cases when two or more antibiotics are used than when either drug is used alone. On the basis of these criteria, it is now universally accepted that synergism has been demonstrated in enterococcic endocarditis with the use of a combination of penicillin and streptomycin in brucellosis when streptomycin has been administered with one of the tetracyclines or with chloramphenicol and in certain cases of micrococcic (staphylococcic) endocarditis when a combination of penicillin and chlortetracycline, or streptomycin and oxytetracycline has been used. Reports of several cases of endocarditis have been published as instances of the effective use of other combinations of antibiotics. These include administration of penicillin and chloramphenicol in endocarditis caused by Streptococcus viridans[6], oxytetracycline and streptomycin in endocarditis due to Hemophilus organisms[7], erythromycin and streptomycin in endocarditis caused by Micrococcus pyogenes var aureus and by streptococci[8], erythromycin, chlortetracycline, and streptomycin in endocarditis produced by enterococcus[9], and penicillin and bacitracin in endocarditis caused by a diphtheroid[10]. Although synergism may have existed in these cases, it was reasonably well proved in two cases only. One of Jones and Yow's[8] patients with micrococcic endocarditis was first given erythromycin alone, which was merely suppressive, later a combination of streptomycin and erythromycin was given, which proved curative. Since streptomycin alone is rarely curative in micrococcic endocarditis, it is likely that the combination brought about cure when neither drug alone would have done so. The patient with endocarditis caused by a diphtheroid bacillus was given penicillin, with resulting suppression of the infection, and recovered after receiving penicillin and bacitracin[10]. Since the infecting organism was resistant to bacitracin in vitro, it is unlikely that bacitracin alone would have brought about recovery.

A number of investigators have shown that, in endocarditis caused by streptococci that are sensitive to penicillin, combined penicillin and streptomycin therapy for 10 days to 2 weeks is at least as effective as the more prolonged therapy with penicillin alone. Some evidence is even available that the case-fatality rate is lower and the relapses are less frequent when the short-term combined therapy is used.

Reports have appeared in which claims were made that certain of the newer antibiotics showed synergism when combined with another antibiotic. These findings have been confined to in vitro and animal studies and even these studies are open to different *interpretations*. English and his associates[11] reported on the combined action of oleandomycin (Matromycin) and tetracycline in the proportion 1 2. In vitro studies on the micro-organisms reported showed 'enhanced activity' of the combination, which varied from less than twice that of the sum of the activities of the individual antibiotics to sixfold (in one case twentyfold) the activities of the individual antibiotics. A fourfold or greater difference was observed in only 7 of 28 strains. No statement was made as to how many strains were examined that did not show such 'synergism'.

Three strains of M pyogenes var aureus and one of Streptococcus pyogenes were studied in mice. A statistically significant enhancement of therapeutic effect by the combination was observed, as compared with the sum of the effects of the individual drugs. This evidence is suggestive enough to warrant further investigation with a number of strains from different human infections and with varying dosage ranges. It must be emphasized, however that synergism in animals, even if established unequivocally, does not necessarily mean that synergism will be observed in human infections. Furthermore, dosage proportions that show synergism in animals may not be the same as those that show synergism in human infections. In fact they may show indifference or even antagonism when used in humans. Finally, the only valid proof of clinical synergism is the unequivocal demonstration by means of adequately controlled studies that superior results are obtained in human infections when the two drugs are used together than when each drug is used singly.

Another study[12] reports in vitro and animal investigations on the combined action of oleandomycin and penicillin. Although synergistic action was observed with certain organisms and in certain proportions, antagonistic action was apparent when other propor-

COUNCIL ON DRUGS

Report to the Council

The Council has authorized publication of the following report. Nonproprietary terminology is used for all drugs that are mentioned, when such terminology is not considered to be generally well known, its initial appearance is supplemented by parenthetic insertion of names known to be applied to commercial preparations.

H. D. Kautz, M.D., *Secretary*

MIXTURES OF ANTIBIOTICS

Harry F. Dowling, M.D., Chicago

The recent marketing of several novel mixtures of antibiotics has revived interest in the value of combinations of antibiotics. Various claims have been made for the superiority of a mixture of two antibiotics over either of the drugs used alone. It is claimed that mixtures of antibiotics should be used for the following reasons: (1) to produce a better therapeutic result than can be achieved by maximal dosage of either antibiotic alone (synergism), (2) to achieve a therapeutic result with nontoxic doses of two antibiotics that would require a toxic dose of either antibiotic alone, (3) to prevent or delay the appearance of resistant strains of infecting organisms, (4) to treat mixed infections in which no single antibiotic is effective against all of the organisms present, and (5) to treat seriously ill patients before a bacteriological diagnosis is made. These claims will be considered in the order in which they are listed.

Synergism and Antagonism

The problem of synergism was ably reviewed by Jawetz and Gunnison[1] in a report to the Council on Pharmacy and Chemistry in 1952, and more extensively elsewhere.[2] Other reviews of this subject were written by Garrod[3] and Dowling, Lepper, and Jackson.[4] In the present report the status of combined antibiotic therapy at the time the previous reports were written will be summarized. Recent studies will then be added and the total picture evaluated.

In experiments in vitro and in animals, when the effect of two drugs acting simultaneously on a microbial population is compared with the effect of either drug alone, the result may be synergism, simple addition, indifference (no increased or decreased action), or antagonism (an effect that is less than that achieved with the most effective of the two drugs acting alone). The term synergism has been defined differently by different investigators. In general, it is agreed that synergism means that the antimicrobial effect obtained from the use of a combination is greater than the sum of the effects of each of the component agents acting alone. The methods used to determine synergism differ greatly, however. The method most commonly used for determining in vitro whether a given combination will produce synergism, antagonism, or indifference is the observation of the amount of each drug and of the drug combination necessary to suppress growth in the test tube or to delay growth for a fixed period of time. The results are expressed as a minimal weight of drug necessary to suppress growth or to delay the appearance of growth. Synergism is then claimed if inhibition of growth is achieved by less than half the minimal inhibitory concentration of one drug, plus half or less than half the minimal inhibitory concentration of the second drug. Biological experiments cannot be done accurately enough to make anything less than a fourfold difference significant, however, this method of reasoning is fallacious because there is no evidence that half the weight produces half the activity of the full amount of the drug. In fact, experimental evidence shows that the opposite is true, namely, that the weight and antibacterial activity do not have a linear relationship.

An in vitro test giving results that most closely parallel those observed in animals and in patients is the subculturing of micro-organisms at intervals after exposure to the drugs and combinations tested. This test determines the rate and completeness of killing. The rapidity with which a combination of antibiotics will kill bacteria in the early hours of the experiment, as compared with the rate of killing produced by the individual antibiotics during the same period, is used as an index of synergism, indifference, or antagonism.

Studies in animals have added another important dimension to the observations. As the proportions of the two antibiotics in a given mixture have been varied, either synergism, indifference, or antagonism has been demonstrated. The evidence from in vitro and animal experiments was summarized by Jawetz and Gunnison[1] by listing antibiotics in two groups: group 1 (primarily bactericidal) containing penicillin, streptomycin, bacitracin, and neomycin (Mycifradin, Myciguent, Neomycin), and group 2 (primarily bacteriostatic) containing chlortetracycline (Aureomycin), oxytetracycline (Terramycin), tetracycline (Achromycin, Panmycin, Polycycline, Steclin, Tetrabon, Tetracyn), chloramphenicol (Chloromycetin), erythromycin (Erythrocin, Ilotycin), and carbomycin (Magnamycin).[5]

From the University of Illinois Research and Educational Hospitals and the Department of Medicine, University of Illinois.

Mixtures in vitro of members of group 1 frequently how synergism sometimes indifference, never antag nism Members of group 2 are neither synergistic nor ntagonistic to each other, but simple additive effects re often observed In other words the same effect is btained by increasing the dose of a single antibiotic s by adding an equivalent amount of another antibiotic in the group When an antibiotic from group 1 s used with an antibiotic from group 2 the effect may e synergism indifference or antagonism Which of hese will occur depends upon such complex factors s the relative amounts of the two antibiotics used in he combination and the susceptibility or resistance of he micro organism to the individual antibiotic In no ase is it possible to predict whether synergism or ntagonism will occur with a given drug combination This can be determined only by actual experiment with a specific drug combination acting on a partic ular strain of the organism Even when a particular strain is used the results may vary depending upon the relative proportions of drugs used

Although there may be exceptions to these generalizations they agree remarkably well with the results of most laboratory investigations How well does clinical experience correlate with this classification and the experiments upon which it is based? In the few well-controlled clinical studies the results have been similar to those obtained in animal experiments and in vitro experiments in which the rate of bacterial killing was used as a *criterion* Correlation has *not* been as good between human infections and tests that show inhibition of growth in tubes containing varying proportions of two antibiotics Several newer tests have been devised to show synergism or antagonism in vitro but no reports of parallel studies of human infection are available Consequently these tests cannot be evaluated at the present time

For clinical purposes synergism means a therapeutic effect obtained with two or more drugs that could not be obtained with either drug alone in full therapeutic doses or a lower case fatality rate in a group of cases when two or more antibiotics are used than when either drug is used alone On the basis of these criteria it is now universally accepted that synergism has been demonstrated in enterococcic endocarditis with the use of a combination of penicillin and streptomycin in brucellosis when streptomycin has been administered with one of the tetracyclines or with chloramphenicol and *in certain cases of micrococcic* (staphylococcic) endocarditis when a combination of penicillin and chlortetracycline or streptomycin and oxytetracycline has been used Reports of several cases of endocarditis have been published as instances of the effective use of other combinations of antibiotics These include administration of penicillin and chloramphenicol in endocarditis caused by Streptococcus viridans[6], oxytetracycline and streptomycin in endocarditis due to Hemophilus organisms[7], erythromycin and streptomycin in endocarditis caused by Micrococcus pyogenes var aureus and by streptococci[8], erythromycin, chlortetracycline, and streptomycin in endocarditis produced by enterococcus[9], and penicillin and bacitracin in endocarditis caused by a diphtheroid[10] Although synergism may have existed in these cases, it was reasonably well proved in two cases only One of Jones and Yow's[8] patients with micrococcic endocarditis was first given erythromycin alone, which was merely suppressive, later a combination of streptomycin and erythromycin was given, which proved curative Since streptomycin alone is rarely curative in micrococcic endocarditis, it is likely that the combination brought about cure when neither drug alone would have done so *The patient with endocarditis* caused by a diphtheroid bacillus was given penicillin, with resulting suppression of the infection, and recovered *after* receiving penicillin and bacitracin[10] Since the infecting organism was resistant to bacitracin in vitro, it is unlikely that bacitracin alone would have brought about recovery

A number of investigators have shown that, in endocarditis caused by streptococci that are sensitive to penicillin, combined penicillin and streptomycin therapy for 10 days to 2 weeks is at least as effective as the more prolonged therapy with penicillin alone Some evidence is even available that the case-fatality rate is lower and the relapses are less frequent when the short-term combined therapy is used

Reports have appeared in which claims were made that certain of the newer antibiotics showed synergism when combined with another antibiotic These findings have been confined to in vitro and animal studies, and even these studies are open to different interpretations English and his associates[11] reported on the combined action of oleandomycin (Matromycin) and tetracycline in the proportion 1 2 In vitro studies on the micro organisms reported showed 'enhanced activity of the combination, which varied from less than twice that of the sum of the activities of the individual antibiotics to sixfold (in one case twentyfold) the activities of the individual antibiotics A fourfold or greater difference was observed in only 7 of 28 strains No statement was made as to how many strains were examined that did not show such synergism

Three strains of M pyogenes var aureus and one of Streptococcus pyogenes were studied in mice A statistically significant enhancement of therapeutic effect by the combination was observed, as compared with the sum of the effects of the individual drugs This evidence is suggestive enough to warrant further investigation with a number of *strains from different* human infections and with varying dosage ranges It must be emphasized however that synergism in animals even if established unequivocally does not necessarily mean that synergism will be observed in human infections Furthermore, dosage proportions that show synergism in animals may not be the same as those that show synergism in human infections In fact they may show indifference or even antagonism when used in humans Finally, the only valid proof of clinical synergism is the unequivocal demonstration by means of adequately controlled studies that superior results are obtained in human infections when the two drugs are used together than when each drug is used singly

Another study[12] reports in vitro and animal investigations on the combined action of oleandomycin and penicillin Although synergistic action was observed with certain organisms and in certain proportions, antagonistic action *was apparent when* other proportions were used Again, there was no evidence that this combination would be superior in human infections to either antibiotic used alone

Proved instances of clinical antagonism have been reported less frequently than proved instances of synergism Antagonism occurs only when certain rigid ratios of antibiotics are present at the site of the infection For this reason, antagonism is not often encountered clinically, since the doses of antibiotics usually administered to patients are much larger than the minimally effective doses The best clinical example of antagonism is found in pneumococcic meningitis, in which penetration of the antibiotics to the site of infection is notoriously poor Lepper and Dowling[13] reported that, when penicillin and chlortetracycline were used together in pneumococcic meningitis, 79% of patients died, whereas only 30% of patients died when penicillin was used alone in the same doses There is some evidence that the combination of chlortetracycline, streptomycin, and sulfisoxazole (Gantrisin) was less effective in meningitis caused by Hemophilus influenzae than was chlortetracycline alone

On the other hand, Ahern and Kirby[14] reported that, when penicillin and chlortetracycline were given in full therapeutic doses to patients with pneumococcic pneumonia, the results were similar to those obtained in patients who received the same doses of penicillin alone In view of the small doses of penicillin that will bring about recovery in this disease, it is obvious that penetration of penicillin to the site of infection is excellent The doses given by Ahern and Kirby, therefore, were excessive It should be noted, however, that, although antagonism was not observed, neither was there any evidence of synergism The results were as good when penicillin was used alone as when chlortetracycline was added

A recent study by Strom[15] demonstrated that antagonism occurred when the concentrations of one or both antibiotics were at or below the minimal effective concentrations He treated three groups, each consisting of 105 patients who had scarlet fever, as follows (1) procaine penicillin G, orally, in doses of 250,000 units three times a day for adults and equivalent dosage for children, (2) 0 5 Gm of chlortetracycline hydrochloride twice a day for adults and equivalent dosage for children, and (3) both antibiotics in the same dosages No difference was observed in the clinical course, number of complications, or rapidity of disappearance of hemolytic streptococci from the pharynx, but the speed and magnitude of the return of streptococci after cessation of treatment was greatest in the chlortetracycline group, least in the penicillin group, and intermediate in the group of patients who received both drugs He had previously shown that the return of streptococci after treatment was associated with the intensity of treatment Accordingly, chlortetracycline apparently antagonized the bactericidal effect of penicillin in these patients with scarlet fever

Antagonism has not been reported in individual cases, although many patients have died of endocarditis or other bacteremias despite treatment with large doses of two antibiotics Some of these deaths could have resulted from antagonism, however, conclusive proof could obviously not have been obtained, since this would have required failure of the patient to recover after use of two antibiotics and successful recovery after use of one alone Because the trend is always to administer one antibiotic first and two or more later, these criteria are never fulfilled

The evidence favoring the use of combinations of antibiotics to obtain better results than the most effective antibiotic alone can be summarized as follows Synergism occurred in the treatment of nonhemolytic streptococcic (including enterococcic) endocarditis when penicillin and streptomycin were used, in brucellosis when streptomycin was used with one of the tetracyclines or chloramphenicol, and in occasional cases of severe micrococci infections when penicillin or streptomycin was used with one of the tetracyclines or chloramphenicol Other combinations may possibly have been synergistic in occasional cases of endocarditis caused by nonhemolytic streptococci, micrococci, or Hemophilus organisms Antagonism has been demonstrated only in pneumococcic meningitis and scarlet fever when the dosages were such that only minimal concentrations of the antibiotics reached the site of infection

Reduction of Toxic Effects

The second reason given for the use of combinations of antibiotics is to achieve therapeutic results with nontoxic doses of two antibiotics that would require a toxic dose of either antibiotic alone Early reports on the use of a mixture of equal parts of streptomycin and dihydrostreptomycin sulfate appeared to show that the frequency of eighth-nerve damage was less than when either antibiotic was used alone in the same total dosage Wier and his associates,[16] however, in a recently published, careful study of 105 patients, reported that deafness was more frequent in patients who received the two drugs, whereas vestibular damage occurred more often in patients who were given comparable doses of streptomycin alone Since deafness is so much more serious than impairment of vestibular function and seems to be more commonly associated with dihydrostreptomycin, it would appear that streptomycin therapy alone should now be regarded as less likely to induce auditory impairment than the use of the combination

Prevention of the Appearance of Resistant Micro-organisms

The third reason for advocating combinations of antibiotics, to prevent the appearance of resistant strains of the infecting organism, has found practical clinical application in the treatment of tuberculosis It is now proper practice to use combinations of two or more of the following drugs streptomycin, isoniazid, and aminosalicylic acid (para-aminosalicylic acid)

Lepper and his associates[17] recently reported that the combination of novobiocin (Albamycin, Cathomycin) and spiramycin delayed for three months the appearance of resistant strains of micrococci in nasal carriers When spiramycin was used alone, the difference in the time of appearance was six weeks The percentage of strains resistant to spiramycin was *eventually as great, whether one or both antibiotics* were used Although the field of antibiotic-resistant micrococci is an important one for the use of such combinations and although results look promising, this method would seem to have limited value for two reasons First, the Micrococcus must be sensitive to both antibiotics before treatment is started, second, in order to prevent the appearance of resistant strains, the two antibiotics should always be administered together rather than singly in a given hospital (and preferably in the entire country) It does not seem likely that the latter objective could be achieved even if it were known to be worthwhile The use of combinations therefore, to delay the appearance of resistant strains will probably be restricted to the treatment of tuberculosis in the foreseeable future

Mixed Infections

The fourth reason given for the use of combinations of antibiotics is to combat the mixed flora of the gastrointestinal tract, the peritonitis that follows soilage from the gastrointestinal tract, and mixed infections of the lower part of the respiratory tract, the skin, and the urinary tract Any of the tetracyclines or chloramphenicol will lower the bacterial count of the intestinal flora as effectively as most or all of the advocated combinations of antibiotics There is good evidence[18] that the simultaneous use of polymyxin B (Aerosporin, Polymyxin B) and neomycin is more effective than either antibiotic alone and perhaps more effective than the tetracyclines and chloramphenicol This combination has the advantage that absorption from the gastrointestinal tract will not occur if proper doses are used, and, therefore, hypersensitivity is unlikely to develop

For the therapy of peritonitis, the tetracyclines have been shown experimentally to be equal and perhaps superior in effectiveness to a widely used mixture of penicillin and streptomycin If the decision is made to use penicillin and streptomycin, however, it is best to administer them separately, this allows the clinician greater flexibility of dosage and route of administration than mixtures previously prepared and dispensed in ampuls

The number of Candida organisms in the stools can be reduced by the use of nystatin (Mycostatin) in conjunction with a tetracycline, as compared with a tetracycline alone It is doubtful, however, whether the large number of candidas in the intestinal tract ever cause an infection Even if they do, all of the micro-organisms in the stool are never eliminated by any single antibiotic or combination of antibiotics When Candida organisms are suppressed, some other organism not affected by the antibiotics used, such as Proteus vulgaris or resistant Micrococcus, may become the predominant micro organism Another argument against the use of nystatin-tetracycline mixtures is that the use of nystatin extensively in a hospital will cause the appearance of nystatin-resistant strains of Candida, which are likely to become predominant in that hospital Thus, nystatin will be useless when it is needed for therapeutic purposes For these reasons, the routine use of nystatin-tetracycline combinations is not considered advisable

For infections of the lower part of the respiratory tract, the best results are obtained in chronic bronchitis and bronchiectasis with one of the tetracyclines or chloramphenicol No evidence is available that these results can be improved with combinations The use of penicillin, or a tetracycline alone, appears to be optimal therapy for lung abscess Accordingly, there is little reason for the use of combinations of antibiotics in mixed infections of the respiratory tract

During infections of the urinary tract, more than one organism is sometimes cultured from the urine Often one organism is important in the infection, the other organisms that are cultured from time to time are occasionally associated with the primary offender or are contaminants obtained in collecting or culturing the urine Repeated cultures and quantitative cultures of the urine will aid in making this differentiation In those instances in which two or more pathogenic organisms are actually causing infection, it may be advisable to use two antibiotics They should be carefully selected for their effectiveness against the infecting strains on the basis of in vitro tests

Mixed infections of the skin present a considerable problem I am unaware of any controlled studies showing that mixtures of antibiotics are more effective than single ones, or indeed more effective than methods of therapy in use before antibiotics were available Certainly it seems advisable to use measures other than administration of antibiotics whenever possible At least antibiotics that are not used systemically should be employed, to prevent hypersensitivity during treatment for a skin infection not dangerous to life An antibiotic may be urgently needed later for a serious systemic infection

Use in Unidentified Infections

The fifth and last reason advanced for the use of combinations of antibiotics is to treat seriously ill patients before a bacteriological diagnosis is made There is no objection to the use of combinations under certain circumstances if such therapy is confined to patients who require immediate treatment and in whom the clinical diagnosis of an infection is reasonably certain and if the antibiotics used are selected to combat the organisms most likely to be causing the infection It is a tragic fact, however, that many patients have been treated with two or more antibiotics who did not need to be treated before a bacteriological diagnosis was available Such a procedure delays proper diagnosis and makes it more difficult Furthermore, hypersensitivity to an antibiotic sometimes occurs under these circumstances Occasionally, resistant forms of organisms appear because the proper combinations were not used or adequate doses were not given, and sometimes the patients are actually suffering from some other disease and not from an infection If antibiotic therapy must be resorted to, an accurate clinical diagnosis is imperative in cases in which laboratory data are not available The possibility of antagonism should also be kept in mind when an antibiotic from Jawetz and Gunnison's group 1 is used with an antibiotic from group 2 Such combinations should not be administered in meningitis or in other disease states in which penetration to the site of infection is poor Each antibiotic should be given in full therapeutic doses

Danger of Carriers

One other drawback to the routine use of mixtures of antibiotics should be mentioned Abundant evidence has now accumulated to show that, in hospitals in which a number of patients are receiving an antibiotic, micrococci resistant to that antibiotic accumulate in the upper air passages of attendants and of patients who have not received the antibiotic From there they may infect wounds, burns, or the respiratory tracts of other patients By this mechanism, the physician has lost the possibility of using that particular antibiotic in serious micrococcic infections

Summary and Conclusions

A review and evaluation on the basis of currently available evidence reveal the following reasons given for the use of mixtures of antibiotics

1 For obtaining a synergistic action, mixtures of antibiotics can be used in a few diseases in which their value has been clinically proved, they may occasionally be useful in a special case outside of this group, but in general these mixtures do not produce a synergistic effect One antibiotic in a combination may even be antagonistic to the other under special circumstances Laboratory tests of the minimal concentrations of antibiotics required to inhibit growth of the causative micro-organism are seldom helpful in determining whether a certain mixture of antibiotics will be effective clinically In fact they may actually be misleading

2 For minimizing toxic reactions by using half-doses of two related antibiotics to achieve equivalent therapeutic results, a mixture of equal parts of streptomycin and dihydrostreptomycin sulfates has been used However, there is recent evidence to indicate that this combination is more likely to produce auditory impairment than do full doses of streptomycin alone

3 For preventing the appearance of resistant strains of tubercle bacilli combinations of two or more of the following drugs are indicated streptomycin, isoniazid, and aminosalicylic acid Mixtures of these anti-infectives are not advised for the control of other bacteria

4 For the treatment of mixed infections or for the disinfection of the intestines prior to abdominal operations, single antibiotics are often as satisfactory as, or superior to, mixtures The intestinal flora may be suppressed preoperatively with mixtures of poorly absorbed antibiotics Combinations of penicillin and streptomycin may be used in peritonitis, if desired However, they are best administered separately, rather than from a mixture containing a fixed ratio, since the latter method may make it difficult to give the optimal dosage of each drug Mixtures of bacitracin and polymyxin B may be applied locally to infections of the skin

5 For treating seriously ill patients before a bacteriological diagnosis is made, proper therapy may occasionally require the concomitant administration of two antibiotics These should be given only after a careful clinical diagnosis has been made and only in doses that would be optimal for each drug if used alone (never in ready-made mixtures). The agents used should be those most likely to be highly effective against the clinically diagnosed infection

In conclusion, the administration of combinations of antibiotics is indicated only in a few highly selected conditions However, they have been advocated and used in other conditions in which they not only do no good but actually may be harmful When combined therapy of antibiotics is indicated, the antibiotics are best given separately, except in the case of mixtures for local application to the skin

MEDICINE AT WORK

HOW AUTHENTIC IS MEDICINE ON TELEVISION?

FIFTY MILLION WEEKLY VIEWERS ARE FINDING OUT—THEY ALSO SEEK ACCURACY IN MOVIE AND RADIO MEDICAL SCENES

For many years Lassie has triumphed over all manner of emergencies on motion-picture film. But neither Lassie nor its owners could solve one problem in the dog's frisky fictional life several weeks ago.

A proposed television script called for Lassie's boy companion to become ill of pneumonia while hiding in a treehouse. Would the family doctor allow him to keep hiding there under adult supervision? Managers of the television show put that question to several physicians. Some replied, "Absolutely not." A few said "Yes." Others said, "Maybe." So as Lassie's bushy tail swept gentle arcs of unperturbed wagging, the producer rushed off a telegram to the American Medical Association: "In our desire to portray medical profession with honesty and sincerity we ask you to give us the definitive professional attitude about this hypothetical case."

Back came a reply in the form of two suggestions: either eliminate the doctor's role, or change the sequence so that a physician—called the next morning—would diagnose pneumonia, treat the boy, and then praise whatever health protection measures had been taken. "Great," said the producer, relieved. "Thanks." Why all this fuss about a brief scene in a half-hour dog story? The answers are more significant than you may imagine.

For one thing, the Lassie show has 29 million viewers, including perhaps a hundred thousand physicians, nurses, dentists, and others in the healing arts. But it is not merely to avoid guffaws, comments of ridicule or general discredit of the program by these people that pains are taken to assure technical medical accuracy. Even more important is the growing public service attitude among producers to portray health situations authentically for the vast field of nonmedical viewers.

"We are not dealing with 'small potatoes' audiences here. In both fiction and fact presentation the voice and face of medicine today are emerging more intimately before more people than at any time in the history of the world. Independent radio and television stations in every region of the country, cooperating with local medical societies, are finding vast and eager audiences for medical shows woven in such varied format as music, interview, drama, panel discussion, question and answer, demonstration, and individual reporting. Network-wise, there was an average of only two medical stories a week on television a year ago, playing to less than 10 million viewers. Now industry sources report, there are eight or more medical-line television shows weekly, having a combined national audience of at least 50 million. And judging by public response, the demand has not yet been satisfied.

From "Hi Fi" to Oxygen

During one week not long ago, television listings included a "Medical Horizons" presentation on arthritis, "Dr. Hudson's Secret Journal" in an episode on appendectomy, a "Dr. Christian" script involving a decision on childbirth, a "hi-fi" show exploring deafness, a documentary on cancer research, and five dramas in such diverse settings as hospital administration, diabetes study, pregnancy, drug experimentation and medical use of oxygen. Is it any wonder that producers want to be certain that no gesture, no part of dialogue, no dramatic sequence in a medical scene is unrealistic or unfair?

Yet, until last year, many a network executive did not realize that professional assistance on a medical script was available. Some retained physicians as consultants for specific shows, just as movie studios have been doing for years. But the occasional need for added specialist consultants often worked against the very use of stories having certain medical aspects.

American Medical Association headquarters in Chicago was one source for counsel, and the New York medical societies were another. Closer by for Hollywood was the Los Angeles County Medical Association, whose cooperation with producers of "Medic" was presenting medical science accurately and compellingly in story format. Because "Medic" was a network show, the Los Angeles doctor-consultants soon were besieged with television, movie, and radio scripts from Hollywood, New York, Chicago, and other parts of the nation. The county society finally came to the A. M. A. for advice. On Feb. 13, 1956, a 12-man Physicians Advisory Committee on Television, Radio and Motion Pictures met for the first time under auspices of the A. M. A. Board of Trustees and Public Relations Department.

Physicians volunteer their services through two groups, one headed by Dr. Robert W. Gentry in Los Angeles and the other by Co-chairman Gerald D. Dorman in New York (95% of all television, radio, and movie productions originate in these two cities). At first, a few producers looked askance at the Committee, speculating that the A. M. A. Might be trying to dictate some scripts and gag others. One executive for the "Dr. Hudson" television series listened coldly to the Committee's offer to help bring greater authenticity to his programs. Weeks later, testing, he asked a routine medical question. The Committee gave a prompt reply. Today, that weekly drama, climbing to greater heights of viewership, is a gem polished regularly with the help of A. M. A. Committee members. The producer is lavish in his praise of the doctors.

Danger of Carriers

One other drawback to the routine use of mixtures of antibiotics should be mentioned Abundant evidence has now accumulated to show that, in hospitals in which a number of patients are receiving an antibiotic, micrococci resistant to that antibiotic accumulate in the upper air passages of attendants and of *patients who have not received the antibiotic* From there they may infect wounds, burns, or the respiratory tracts of other patients By this mechanism, the physician has lost the possibility of using that particular antibiotic in serious micrococcic infections

Summary and Conclusions

A review and evaluation on the basis of currently available evidence reveal the following reasons given for the use of mixtures of antibiotics

1 For obtaining a synergistic action, mixtures of antibiotics can be used in a few diseases in which their value has been clinically proved, they may occasionally be useful in a special case outside of this group but in general these mixtures do not produce a synergistic effect One antibiotic in a combination may even be antagonistic to the other under special circumstances Laboratory tests of the minimal concentrations of antibiotics required to inhibit growth of the causative micro-organism are seldom helpful in determining whether a certain mixture of antibiotics will be effective clinically In fact, they may actually be misleading

2 For minimizing toxic reactions by using half-doses of two related antibiotics to achieve equivalent therapeutic results, a mixture of equal parts of streptomycin and dihydrostreptomycin sulfates has been used However, there is recent evidence to indicate that this combination is more likely to produce auditory impairment than do full doses of streptomycin alone

3 For preventing the appearance of resistant strains of tubercle bacilli, combinations of two or more of the following drugs are indicated streptomycin, isoniazid, and aminosalicylic acid Mixtures of these anti-infectives are not advised for the control of other bacteria

4 For the treatment of mixed infections or for the disinfection of the intestines prior to abdominal operations, single antibiotics are often as satisfactory as, or superior to, mixtures The intestinal flora may be suppressed preoperatively with mixtures of poorly absorbed antibiotics Combinations of penicillin and streptomycin may be used in peritonitis, if desired However, they are best administered separately, rather than from a mixture containing a fixed ratio, since the latter method may make it difficult to give the optimal dosage of each drug Mixtures of bacitracin and polymyxin B may be applied locally to infections of the skin

5 For treating seriously ill patients before a bacteriological diagnosis is made, proper therapy may occasionally require the concomitant administration of two antibiotics These should be given only after a careful clinical diagnosis has been made and only in doses that would be optimal for each drug if used alone (never in ready-made mixtures) The agents used should be those most likely to be highly effective against the clinically diagnosed infection

In conclusion, the administration of combinations of antibiotics is indicated only in a few highly selected conditions However, they have been advocated and used in other conditions in which they not only do no good but actually may be harmful When combined therapy of antibiotics is indicated, the antibiotics are best given separately, except in the case of mixtures for local application to the skin

MEDICINE AT WORK

HOW AUTHENTIC IS MEDICINE ON TELEVISION?

FIFTY MILLION WEEKLY VIEWERS ARE FINDING OUT—THEY ALSO SEEK ACCURACY IN MOVIE AND RADIO MEDICAL SCENES

For many years Lassie has triumphed over all manner of emergencies on motion-picture film. But neither Lassie nor its owners could solve one problem in the dog's frisky fictional life several weeks ago.

A proposed television script called for Lassie's boy companion to become ill of pneumonia while hiding in a treehouse. Would the family doctor allow him to keep hiding there under adult supervision? Managers of the television show put that question to several physicians. Some replied "Absolutely not." A few said "Yes." Others said, "Maybe." So as Lassie's bushy tail swept gentle arcs of unperturbed wagging, the producer rushed off a telegram to the American Medical Association: "In our desire to portray medical profession with honesty and sincerity we ask you to give us the definitive professional attitude about this hypothetical case."

Back came a reply in the form of two suggestions: either eliminate the doctor's role or change the sequence so that a physician—called the next morning—would diagnose pneumonia, treat the boy and then praise whatever health protection measures had been taken. "Great," said the producer, relieved. "Thanks." Why all this fuss about a brief scene in a half-hour dog story? The answers are more significant than you may imagine.

For one thing, the Lassie show has 29 million viewers, including perhaps a hundred thousand physicians, nurses, dentists, and others in the healing arts. But it is not merely to avoid guffaws, comments of ridicule or general discredit of the program by these people that pains are taken to assure technical medical accuracy. Even more important is the growing public service attitude among producers to portray health situations authentically for the vast field of nonmedical viewers.

We are not dealing with "small potatoes" audiences here. In both fiction and fact presentation, the voice and face of medicine today are emerging more intimately before more people than at any time in the history of the world. Independent radio and television stations in every region of the country cooperating with local medical societies, are finding vast and eager audiences for medical shows woven in such varied format as music, interview, drama, panel discussion, question and answer, demonstration, and individual reporting. Network-wise, there was an average of only two medical stories a week on television a year ago, playing to less than 10 million viewers. Now, industry sources report, there are eight or more medical line television shows weekly, having a combined national audience of at least 50 million. And, judging by public response, the demand has not yet been satisfied.

From "Hi Fi" to Oxygen

During one week not long ago, television listings included a "Medical Horizons" presentation on arthritis, "Dr Hudson's Secret Journal" in an episode on appendectomy, a "Dr Christian" script involving a decision on childbirth, a "hi-fi" show exploring deafness, a documentary on cancer research, and five dramas in such diverse settings as hospital administration, diabetes study, pregnancy, drug experimentation, and medical use of oxygen. Is it any wonder that producers want to be certain that no gesture, no part of dialogue, no dramatic sequence in a medical scene is unrealistic or unfair?

Yet, until last year, many a network executive did not realize that professional assistance on a medical script was available. Some retained physicians as consultants for specific shows, just as movie studios have been doing for years. But the occasional need for added specialist consultants often worked against the very use of stories having certain medical aspects.

American Medical Association headquarters in Chicago was one source for counsel, and the New York medical societies were another. Closer by for Hollywood was the Los Angeles County Medical Association, whose cooperation with producers of "Medic" was presenting medical science accurately and compellingly in story format. Because "Medic" was a network show, the Los Angeles doctor-consultants soon were besieged with television, movie, and radio scripts from Hollywood, New York, Chicago, and other parts of the nation. The county society finally came to the A M A for advice. On Feb 13, 1956, a 12-man Physicians Advisory Committee on Television, Radio and Motion Pictures met for the first time under auspices of the A M A Board of Trustees and Public Relations Department.

Physicians volunteer their services through two groups, one headed by Dr Robert W Gentry in Los Angeles and the other by Co-chairman Gerald D Dorman in New York (95% of all television, radio, and movie productions originate in these two cities). At first, a few producers looked askance at the Committee, speculating that the A M A Might be trying to dictate some scripts and gag others. One executive for the "Dr Hudson" television series listened coldly to the Committee's offer to help bring greater authenticity to his programs. Weeks later, testing, he asked a routine medical question. The Committee gave a prompt reply. Today, that weekly drama, climbing to greater heights of viewership, is a gem polished regularly with the help of A M A Committee members. The producer is lavish in his praise of the doctors.

—"Dr Mike,' a dramatic television series being prepared for fall debut

—"Medical Reporter," a San Francisco radio serial

—A series of filmed television shows on psychiatry, written by prize-winning author Paddy Chavevsky

—At least a half-dozen feature-length movies, such as "Hatful of Rain,' "Three Faces of Eve,' 'The Story of Mankind,' 'Prisoner in Paradise, and "Bellevue Is My Home'

There is no A M A sponsorship in any of these presentations but the A M A does produce a number of films and sound recordings for broadcast on "public service time' Its latest film, "Even for One (showing the "human' side of a doctor's practice) has been televised in 125 cities in three months' time, attracting one million viewers

In addition, hundreds of radio stations across the land use some of their unsponsored time to play authoritative A M A transcriptions on a wide field of health topics These range from diet to heart disease, from antibiotic drugs to accidental poisoning, from sketches of famous physicians to child care and aging

All these radio offerings by the A M A 's Bureau of Health Education are being supplemented by a dramatic new transcription series coming out this month, in which eminent surgeons in 13 different regions of the U S describe procedures on-the-spot as they work in operating rooms

Radio is an equally potent force for medicine outside the U S This is shown by the surprisingly large amount of mail which somehow reaches through the Iron Curtain to Radio Free Europe's Radio Doctor,' the most widely listened to of all programs broadcast from the free world Most of the letter-writers plead for drugs for arthritis, multiple sclerosis, tuberculosis, and urologic diseases

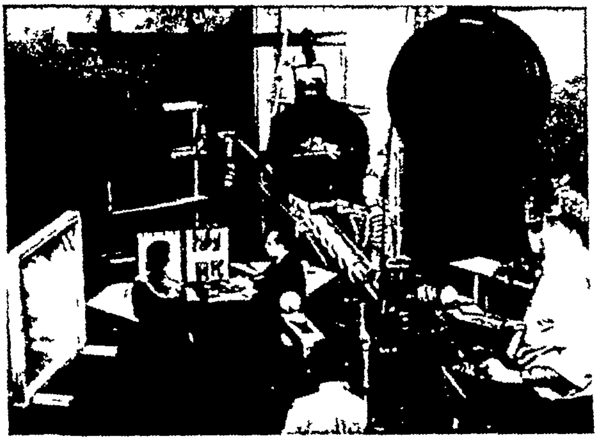
A M A as Pioneer

While the Committee in Los Angeles and New York represents a new approach to greater authenticity, the A M A (sometimes in cooperation with pharmaceutical firms) long has helped tell medicine's story in mass audiovisual communications It has used radio for public information for over a quarter of a century It helped pioneer medical presentation on television more than a decade ago, and on closed-circuit color television in 1949 The A M A 's office of motion pictures and medical television often has been consulted on technical phases of production, both for public view and for showings limited to medical groups

But it is at the local medical society level that authenticity in television achieves its warmest "personal" touch You feel it as members of the Medical Society of the County of New York feature real diagnoses and real treatment for a group of real patients before live television cameras (this also has been done in Seattle and other cities) You sense it as the Winnebago County Medical Society in Rockford, Ill , televises mass visual eye tests for school-age children Doctors of the Medical Society of Milwaukee County let their WTMJ-TV viewers peer through a microscope, watch electrocardiographs in operation, and examine detailed sections of the body through the obliging cooperation of an anatomic mannikin from the Marquette medical school

Audience response to some local medical shows seems boundless, much to the pleasant surprise of physicians and studio officials A few weeks ago in Buffalo, five doctors offered to answer questions from a television audience on dangers of obesity Nearly 18,000 calls flooded the broadcasting station switchboard A similar reaction developed in Seattle earlier this year when a program, 'Call the Doctor,' drew hundreds of questions on the same topic

Four years ago, when WHAS-TV in Louisville, Ky , made the first American telecast of lung cancer surgery, thousands of viewers suddenly became health-conscious Within a few weeks there developed an unprecedented voluntary demand for chest x-rays Blood donations increased People who had been hesitant about reporting for routine physical examinations went to their doctors A recent A M A survey showed that, among 93 county and 17 state medical associations working with local television stations, the most popular type of program format was a panel of physicians with a lay moderator



Camera and mike move in for a close up of local demonstration program televised by WTMJ-TV in coop[illegible]on with Medical Society of Milwaukee County

At the same time there is evidence of more imaginative approaches to television audiences Several societies are laying plans to dramatize medical topics in cooperation with local 'little theater' groups Dr James Rogers Fox of the Minnesota State Medical Association hopes to promote an "Association of Medical Radio-Television' as a vehicle for exchanging data on future programs, problems, and ideas for local medical societies

Grass-roots interest in television as a growing medium for relaying medical authenticity has reached such proportions that the A M A and the National Association of Radio and Television Broadcasters plan to co-sponsor a workshop this fall for representatives of medical societies and allied health groups A committee of broadcasters is being set up to help outline the best use of health shows on unsponsored time

This spirit of cooperation between the medical profession and the television industry—whether it be in Los Angeles or in Onondaga County, New York—is helping arouse today's mammoth public appetite television shows with a medical flavor Just so long the menu includes authenticity with the basic ingredients of action and suspense, the diet will balanced for good health

There seem to be limitless varieties of medical story lines, and for that reason many branches of the profession are represented in the group In New York, Dr Dorman has an industrial health practice, his Committee colleagues are Hospital Administrator Henry Fineberg and Surgery Professor Renato Azzari Co-chairman Gentry in Los Angeles is a chest surgeon Committee members there are Drs Vincent Askey (surgeon, Speaker of the A M A House of Delegates), Dudley Manchester Cobb Jr (general practitioner), Eugene F Hoffman (urologist), Richard O Myers (pathologist), Marcus H Rabwin (surgeon), Charles C Stenley (internist), James F Regan (surgeon), and Edward T Tyler (infertility specialist) For 10 years, in what he calls "a hobby," Dr Tyler has written top-flight material for radio and television shows, including "Medic," NBC spectaculars, and the Groucho Marx show

Advisors, Not Censors

"The primary purpose of this committee is assistance," says Dr Gentry "We are making ourselves available as advisors, not imposing ourselves as censors ' This A M A concept of "help not yelp" is welcomed warmly by producers and network executives Now they, not alone the doctors, are recognizing the hazard of overdramatization in medical-line scripts They, not alone doctors, are spying the pitfalls in such phrases as 'miracle pill" and 'wonder drug ' They, not alone doctors, are becoming leery of some sponsors' wild claims for sedatives and reducing pills

Other lay groups also are hitting the misleading medical commercials Last month the Federal Trade Commission's new radio-television unit filed complaints of false advertising against three national distributors of arthritis and rheumatism medicines At about the same time, the industry's Television Code Review Board decided that the words, 'a dramatization," should be sustained (rather than just flashed) on television screens during commercials which carry statements by actors portrayed as physicians, dentists, or nurses

Whenever the opportunity arises we try to advise portrayal of realistic medical situations," says Dr Gentry "One writer not long ago worked his story around a series of dramatic but truly weird medical symptoms He offered his script and asked us to come up with a disease to fit the symptoms There was none" Among suggestions to television producers who have requested script review are these

—"Doctor should also check shock, pulse, blood pressure, and feel abdomen and reflexes The patient should be complaining of pain in abdomen"

—"A doctor should not be calmed down by a police man"

—"A sedative is usually not administered by hypo It would be better to give a capsule with a glass of water"

—"A patient hanging between life and death would not be left unattended"

At the same time, Committee members realize tha medical fiction need not always conform to the usua practice of medicine—at the expense of certain ele ments of drama For example, after reviewing on script, they noted "Although the committee was of th opinion that 1) it is unlikely that a doctor woul operate on a member of his own family, and 2) th training period necessary for the performance of suc surgery would be greater than shown, it was agree that a certain degree of dramatic license must be per mitted in a program of this nature We are sendin a letter to the producers commending them on an ex cellent job"

Help, Not Hinder

This sort of constructive viewpoint goes a long wa toward removing any "stodgy' label One produce had to be assured that the word "urine" in a script wa perfectly acceptable for public understanding, par ticularly in reference to diabetes Another, seeking t best portray the use of animals in medical researc bubbled with enthusiasm when the Committee sug gested he refer to the true story of how silver nitrat drops in the eyes of kittens helped prove that thou sands of newborn babies need not lose their sight

As producers in the audiovisual arts chart the pub lic's growing demand for medical-line presentation demands on the A M A Committee become greate In recent weeks there have been conferences on gen eral liaison at the request of movie studio officials, o the Alliance of TV Producers, and of the Scree Writers Guild Meanwhile, expert medical counsel i being sought freely and given freely for a whole ne group of motion picture and television shows now i various stages of production These include

Left, a hospital scene from the A M A-produced television film, Even for One *Right* Los Angeles Contingent of the A M A s Advisory Committee listens to medical script problem of commercial television Film Producer Leal Grunke (standing)

—"Dr Mike,' a dramatic television series being prepared for fall debut

—"Medical Reporter," a San Francisco radio serial

—A series of filmed television shows on psychiatry, written by prize-winning author Paddy Chayevsky

—At least a half-dozen feature-length movies, such as "Hatful of Rain," 'Three Faces of Eve,' "The Story of Mankind,' 'Prisoner in Paradise, and "Bellevue Is My Home'

There is no A M A sponsorship in any of these presentations, but the A M A does produce a number of films and sound recordings for broadcast on "public service time' Its latest film, "Even for One' (showing the "human' side of a doctor s practice), has been televised in 125 cities in three months' time, attracting one million viewers

THE "SUMMER ROUND UP" GROWS UP

GUEST EDITORIAL

Henry F. Helmholz, M.D.

Since the "Summer Round-up" of children started in 1925, the National Congress of Parents and Teachers (P. T. A.) has continually expanded its health interests. When, recently, further expansion was indicated, the National Congress turned again to the medical and allied professions for advice, as it had done in working out plans for the Summer Round-up. On January 21, 1956, 20 organizations and government agencies concerned with child health sent representatives to a conference in Chicago, for discussion of "The Periodic Health Appraisal for Children from Birth Through High School." Special emphasis was placed on ways in which the national P. T. A. and state congresses of parents and teachers might most effectively cooperate in a program of the kind proposed.

Out of this meeting came the following recommendations:

> I. That the National Congress of Parents and Teachers adopt a policy supporting and encouraging a program of continuous health supervision of children from birth through their school experience, rather than only a program of single appraisal on school entrance [Summer Round-up].
>
> II. That the National Congress of Parents and Teachers recommend to its local units a promotional and educational program that will tend to bring children and their parents into effective contact with the health resources of the community.
>
> Wherever possible, these should be the physician and dentist who normally serve that child or family, whether they be working in private practice or in a community health service.

In such a program "the role of the parent-teacher association will be to acquaint parents with the means of effectively utilizing the resources available to meet the health needs of children, beginning at birth and continuing through the school years. The parent-teacher association also should work with the professions and agencies of the community in planning and carrying out such a program."

This program was adopted by the National Congress of Parents and Teachers at its annual meeting in May, 1956. Once more the National Congress, which works for the best interests of children attending public schools, has reached a milestone in its long history of cooperation with the health service professions. Again it has increased the opportunity for physicians to work closely with children and their parents, as these parents become better informed about the values derived from child health supervision on a continuing basis at the hands of the family medical advisor.

The American Medical Association and the National Congress of Parents and Teachers have enjoyed a third of a century of cooperation in protection of child health through the Summer Round-up of children. This program, as conceived in 1925, was a means of assuring the health of children who were entering school for the first time. Thus, they might be enabled to benefit to the maximum from their education. Introduction of the round-up, coming when there was renewed interest in child health after World War I, did a great deal to bring apparently well children under the scrutiny of physicians, many of whom were just beginning fully to appreciate that vaccination against smallpox was not the only preventive measure that could be applied in medical practice. At this time the National Congress and the American Medical Association were mutually helpful. Throughout its many thousands of local units, the National Congress promoted the desirability of preventive medical care and examinations by physicians. The American Medical Association, on its part, encouraged physicians to join in the program and provided the National Congress with several-hundred-thousand examination forms for physicians to use. The program became so popular that most schools still require physical examinations of all entering pupils, and the resulting interest in child health has strengthened the entire school health program.

For nearly half a century, moreover, the American Medical Association has promoted sound school health programs through the joint committee that it formed with the National Education Association on health problems in education. For the past decade the Bureau of Health Education of the American Medical Association has had on its staff physicians and educators promoting interprofessional cooperation in solving health problems of school-age children. And now comes another opportunity to strengthen the total child health program by having the millions of members of the local P. T. A. supporting the concept of continuous health supervision of children throughout their entire developmental period. This unusual opportunity to counsel with children and their parents will be welcomed by physicians everywhere.

LAOS MEDICAL MISSION

About eight months ago, young Dr. Thomas A. Dooley returned to Laos in the Far East, to continue the great work he had undertaken while a Navy medical officer caring for and helping refugees who were trying "to escape, to crack through this [iron and bamboo] curtain and achieve or regain their liberty."

While a Navy officer, he had improvised a medical camp at Haiphong in North Viet-Nam during this flight for freedom in that region. In an editorial in THE JOURNAL, September 1, 1956, he said, "I saw

---

Health Chairman, National Congress of Parents and Teachers.

600,000 who fled The memory returns like a searing flame Their anguish Then panic Their tears Their haggard women The death No one who has ever witnessed such a heartbreaking exodus will forget it for the rest of his life'

Dr Dooley wrote also a widely read book, 'Deliver Us from Evil,' in which this experience was described, and the royalties from this book are being used to help finance his current work in Laos, a mission that has the approval of the State Department, the International Cooperation Administration, and the Laotian government Elsewhere in this issue of THE JOURNAL (page 90) is a letter from Dr Dooley, describing what he and his three American assistants have been accomplishing since his return to the Far East, in a region which can be reached by taking a 'PAA plane, then fly 10,000 miles to Bangkok, Thailand, transfer and fly 400 miles north to Vientiane, and then drive eight hours through the jungle to us' Dr Dooley has spent nearly three years in Asia (with a five-month break) He expects, when he has done his part in this great mission to come home and go into private practice He feels that physicians have a special calling to help underdeveloped communities of the world which are threatened by communism Physicians also are in a position to implement our foreign policy of aid to the multitudes of mankind behind the iron curtain to whom liberty and freedom are a pounding, ever-present dream Dr Dooley's experience and high purpose may inspire other young men to go to parts of threatened Asia to take part in this great medical mission and to be salesmen for democracy

MEDICINE'S FIFTY MILLION "FANS"

Any good script writer can create a yarn with suspense and action But in a medical story—be it drama or documentary—authenticity must be searched out Another Medicine at Work article (this issue, page 49) tells how the critical tastes of 50 million weekly viewers of televised medical scenes are reflected in producers who demand utmost medical accuracy Similar high standards of genuineness are being set for movie and radio presentations

A new committee of the American Medical Association is providing authoritative answers sought by these producers for their scripts One result of this voluntary liaison between the medical profession and the entertainment industry is a sharpened awareness of health among television, movie, and radio audiences—and a clearer public understanding of medicine's public service role This, in turn, is whetting the public appetite for more programs about doctors and their work

Herein lies both a phenomenon and a challenge Facing the collective television screen is an unprecedented picture of millions of Americans gazing upon medicine almost daily in a face-to-face, informal, and understandable presentation, on screen are the words and actions which might either highlight or dim the true portrayal of physicians as neighbors, scientists, and benefactors It is to the great credit of producers and studio executives that the profession is seen fully and faithfully in its natural and human light—neither glorified nor degraded

THE UNPALATABILITY OF THERAPEUTIC DIETS

A major problem of diet therapy is unpalatability of the diet, with consequent lack of patient cooperation Diets can be made more palatable by providing for the use of a wide variety of acceptable seasonings The report of Elvehjem and Burns [1] to the Council on Foods and Nutrition of the American Medical Association drew attention to the role spices could play in this regard The report consisted of a study of the sodium content of commercial spices and suggested their use in the preparation of sodium-restricted diets Prior to Elvehjem and Burns' report the sodium content of the common spices was unknown, hence they could not be used with assurance that they made no significant addition to the sodium content of the foods they seasoned Following closely on this report came the recommendation of a committee of the American Heart Association [2] of a long list of acceptable seasonings for use in both sodium-restricted and calorie-restricted diets for cardiac patients The list included, in addition to spices and herbs, such other flavorings as lemon juice, vinegar, vanilla, saccharin, cyclamate (Sucaryl), onion, and garlic A longer list is recorded in a report of a committee of the Food and Nutrition Board, National Research Council [3]

More recently, Gray and co-workers [4] reported a study on the effect of spice ingestion on the healing time of peptic ulcer Fifty patients with active peptic ulcer, with craters demonstrable by x-ray, were maintained on a routine ulcer regimen, including a progressive ulcer diet interval feedings, antispasmodics, and antacids They were given, in addition, a capsule containing a spice, the nature of which was unknown to the patient, three times daily, with meals The dose of spice was determined by its usage in highly spiced recipes Four slices of cinnamon toast, for example, requires about 0 9 Gm of cinnamon The patients were thus given 0 9 Gm of this spice three times daily This test was reasonably severe, because the amount of spice used was the amount recommended in rather highly spiced recipes and it was given in capsules that dissolved in the stomach, releasing the dry spice directly

The spices tested included cinnamon, nutmeg, allspice thyme, sage, paprika, caraway seed, chili pepper, cloves, black pepper, and mustard seed Symptoms developed in only five patients in this group during the administration of spices two with administration of black pepper, one with chili pepper, one with nutmeg, and one with ground mustard seed

These studies suggest that some of the milder spices may be used in moderation to improve the flavor and acceptability of therapeutic diets, even in patients with peptic ulcer

ORGANIZATION SECTION

REPORTS OF OFFICERS

The following reports will be presented to the House of Delegates of the American Medical Association at its session to be held in New York in June.

REPORT OF THE BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association

The following report of the Board of Trustees is respectfully submitted.

Financial Statement

The official 1956 reports of the Treasurer and of the Association's auditors appear as a part of this report of the Board of Trustees.

American Medical Association dues payments from approximately 136,000 members together with subscription receipts from THE JOURNAL, specialty journals and *Today's Health* amounted to $5,192,650. This figure exceeded 1955 receipts from the same sources by $268,344.

Advertising revenue from all publications amounted to $4,943,003 compared with $4,184,277 received in 1955, or a gain of $758,726. THE JOURNAL and specialty journals accounted for $756,712.

Investments of the Association earned $293,112 in 1956 compared with $239,298 in 1955. The approximate over-all annual yield was 2.96%. Other income amounted to $174,070.

Printing and publishing costs of Association periodicals, books and pamphlets amounted to $5,222,444, an increase over 1955 of $262,784, due principally to an increase in production of all periodicals.

The expenditures of the Councils, Bureaus, and related activities listed in schedule 1 of the Auditor's Report amounted to $3,727,966, an increase of $85,846 over 1955.

Other expenses amounting to $355,972, include cash discounts, net maintenance of idle plant, unallocated expenses, legal expense, and net cost of conducting the Chicago and Seattle meetings.

Net income from the 19th Edition American Medical Directory sales and the Directory Report Service amounted to $425,683. Other nonrecurring income amounted to $84,811.

The Association's contribution for 1956 to the American Medical Education Foundation was $125,000. Total Association contributions to the Foundation amount to $2,325,000.

The net amount transferred to Capital for 1956 was $71,947 after providing for additional reserves of $1,610,000.

Marketable securities carried at cost are valued at $8,459,351 exclusive of securities held in the American Medical Association Research Fund of $1,491,060. The total amounting to $9,950,411 at Dec. 31, 1956, compares with $8,010,371 at Dec. 31, 1955.

A general classification of securities will be found in the balance sheet contained in the Auditor's Report.

Report on Matters Referred by House of Delegates

Narcotic Addiction.—In June 1954 Dr. Andrew A. Eggston, New York, submitted a resolution which proposed that the American Medical Association favor the legalization of distribution of narcotics to addicts under the following safeguards: (1) establishment of narcotic clinics in cities where needed under the aegis of the Federal Bureau of Narcotics, (2) registration and fingerprinting of narcotic addicts, (3) keeping of accurate records, (4) administering optimal doses at regular intervals to addicts at cost or free, (5) prevention of self-administration, (6) attempt cures through voluntary hospitalization if possible, and (7) avoidance of forceful confinement.

This resolution was referred to the Reference Committee on Hygiene, Public Health and Industrial Health. The Reference Committee because of the complexity of the problems involved thought the matter should be referred to the Board of Trustees for further reference to an appropriate group of experts for detailed consideration, the results of such studies to be reported at a subsequent meeting of the House of Delegates.

The Board of Trustees referred the resolution to the Council on Pharmacy and Chemistry for detailed consideration.

The Board agreed with the report of the Council that the problem was being handled too exclusively as a police problem without sufficient emphasis on its most important medical aspects and referred the problem to the Council on Mental Health for thorough exploration.

In April, 1955, the Council established a Committee on Narcotic Addiction. This committee has made a thorough review of all material available concerning the operation of clinics which dispensed narcotics during the period 1919-1923, has studied proposals for legal dispensing of narcotics to addicts, has conferred with persons with expert knowledge of the medical, social and legal aspects of addiction, and has studied testimony and statements of persons holding various views on the question. It has also reviewed the voluminous material contained in the reports of the Subcommittee on the Improvement of the Federal Criminal Code, U. S. Senate and reports of the Subcommittee on Narcotics of the House of Representatives.

The following recommendations of the Council on Mental Health were submitted to the Board of Trustees and are quoted below for action by the House of Delegates.

(1) Improvement of the care of addicts.—It is recommended that the American Medical Association continue to study and to support reasonable proposals designed to improve the treatment and prevention of drug addiction. Such measures might include: (*a*) Development of institutional care programs in cities and states with significant problems. (*b*) Study of various means to obtain institutional care in states with small addiction loads. One such proposal is for several states to set up an institution which would be operated jointly. (*c*) Development of programs for intensive postinstitutional treatment of addicts. Such measures would include supplying of various social services, vocational rehabilitation, and, where possible, psychotherapy to addicts for adequate periods following discharge from institutions. In many instances, available facilities in other programs might be utilized. States with serious problems should develop special programs for addiction. (*d*) Development of methods for commitment of addicts to institutions by civil action rather than through actions in the criminal courts. In this connection the Council further recommends that where civil commitment procedures can be used, criminal sentences for addicts who are guilty only of illegally possessing and obtaining opiates, marihuana and cocaine should be abolished. Criminal sentences for illegal sale of narcotics should be retained but persons who are addicts and who are sentenced for such offenses should have the same opportunity for probation and parole as is afforded offenders against other laws. Mandatory minimum sentences for addict violators would interfere with the possible treatment and rehabilitation of addicts and therefore should be abolished. (*e*) The Council strongly recommends that the policy of voluntary admissions for the treatment of addiction should be continued, extended and encouraged. (*f*) Continued support and expansion of mental health programs. Because of the importance of psychiatric factors in addiction such programs should eventually have an effect in reducing addiction even though not specifically aimed at that problem.

(2) It is recommended that the American Medical Association support proposals for increased research on the problems of addiction. One of the current difficulties in formulating adequate programs is lack of knowledge which can be gained only through research. Support should be given not only to basic laboratory investigations but also to continuation of sociological studies and to an intensive program of clinical research based on adequate facilities for following addicts after institutional discharge. Such research might yield results that would be valuable in areas other than addiction.

(3) Clinic plans—In view of all of the available evidence at the present time it does not seem feasible to recommend the establishment of clinics for the supply of drugs to addicts This is true for the Eggston resolution and the plan of the New York Academy of Medicine even though there are many aspects of these plans that could be looked upon with favor This opinion should be subject to frequent review in accordance with new scientific knowledge that may become available

(4) It is recommended that the American Medical Association continue to study the narcotic laws with the view of further clarification of the rights and duties of physicians and allied professional persons in the handling of addicts The phrases in the current law "in the course of professional practice only" and "prescription" remain vague and confusing, despite Supreme Court decisions Regulations on dispensing drugs to addicts should be eased so that the patients can have a reasonable time to arrange their affairs prior to entering a hospital for treatment The 1924 resolution of the House of Delegates should be revised Consideration should be given to broadening the resolution to include a plan endorsing regulations somewhat similar to those currently in force in England

Statement of A M A Policies—In November, 1956, a resolution on annotation of American Medical Association policies was introduced into the House of Delegates by Dr Robert N Larimer on behalf of the Iowa State Medical Society and referred to the Reference Committee on Miscellaneous Business

The House of Delegates adopted a revised resolution to the effect that the Board of Trustees continue to investigate the practicability of developing a statement of policies of the A M A and to arrange for the periodic publication of revised versions of that statement the frequency of revisions to be determined by the Board

The Board of Trustees would call attention to the fact that the words "current policies" mean policies which date back to 1847, since the House of Delegates has never adopted a policy of automatically rescinding all actions prior to an arbitrary date

An abstract of all policies of the House of Delegates is currently being prepared by a professionally trained librarian in the medical sciences This volume which should be ready for distribution at the end of the current year, will cover all House actions from 1847 to the present time It will be an encyclopedia with abstracts alphabetically arranged and supplemented by a detailed index and, to assure continuity, supplements will be published at five-year intervals with a cumulative index

The Board of Trustees feels that annual revision of such a volume is not feasible unless the House adopts a policy of periodically rescinding all of its previous actions

Veterans Affairs—The Board of Trustees considered resolution 12 on veterans affairs and 23 on Veterans Administration hospitals adopted by the House of Delegates at the Seattle meeting requesting the Secretary of the Association to obtain from each state testimony or record of each known case that violates VA Regulation 6047-D 1

These resolutions were transmitted to the constituent medical associations through the medium of the Secretary's Letter (Jan 11, 1957) The Council on Medical Service has been given the responsibility of following through on the replies received from the states or others who know of violations of this regulation

Liaison Between Organized Medicine and Professional and Lay Groups—Resolution 20 which was introduced by the Michigan delegation into the House of Delegates at the Seattle meeting recommended the establishment of an A M A Office of Liaison, reporting directly to the Secretary and General Manager, whose duty it would be (1) to seek out all possible avenues of communication and coordination of effort with other recognized groups professional and lay, which have interests in common with the medical profession, (2) to determine those methods whereby, through administrative contact, common professional aims and purposes can be advanced to mutual advantage and (3) to aid the development of such liaison on a continuing basis subject to the approval of the Board

The Board of Trustees calls to the attention of the House of Delegates the fact that the Committee on Relationships Between Medicine and Allied Health Agencies was established some time ago and is active in this area In addition, the officers councils, committees and departments within the American Medical Association are constantly developing channels of communication and promoting coordinated effort in carrying out the policies of the Association The Board feels that a specific liaison office to supplement these many liaison activities is not necessary

Hospital Design and Construction—In accordance with the action taken by the House of Delegates in Seattle to the effect that the A M A join with the American Hospital Association and the American Institute of Architects in their proposed study of hospital design and construction the Board of Trustees appointed Dr William A Hyland of Michigan as the Association's representative in any discussions which may take place relative to this subject

Public Law 880—Resolution 25 on the administration of Public Law 880, authorizing the provision of cash benefits for disabled persons, was considered by the Board of Trustees

About six months ago a Committee on Medical Rating of Physical Impairment was established by the Board of Trustees Believing that this resolution falls within its purview the Board referred resolution 25 to that committee for study and recommendations As soon as a report is received it will be transmitted to the House of Delegates

Rehabilitation Consultation Service—In December, 1955 a resolution, approved in principle by the House of Delegates recommended that an integrated consultation service to state societies be established which would outline a policy of procedure for the guidance of local professional groups in dealing with the total program of rehabilitation

The Board of Trustees referred the resolution to its Committee on Rehabilitation, established in 1956 That committee at its meeting on Dec 14 1956 reported to the Board that it has taken cognizance of the resolution and will implement it insofar as it is practicable and possible

Referral of Resolutions—In accordance with action taken by the House of Delegates in Seattle, the Board referred the following resolutions to the council as indicated

Resolution 8—Preretirement financing of health insurance for retired persons—Council on Medical Service

Resolution 22—Fluoridation of public water supplies—Council on Drugs and Council on Foods and Nutrition

Resolution 26—Medical care plans—Council on Medical Service

Supplementary Report D on radioactive isotopes—Council on Medical Physics

Annual and Clinical Meetings

The following places and dates have been approved by the House of Delegates and the Board of Trustees for the Annual and Clinical Meetings of the Association

Annual Meetings 1958—San Francisco June 23-27, 1959—Atlantic City June 8-12, 1960—Chicago, June 6-10

Clinical Meetings 1957—Philadelphia Dec 3 6, 1958—Minneapolis Dec 2-5, 1959—Dallas

Supplementary Reports

Supplementary reports on certain subjects that have been referred to the Board of Trustees by the House of Delegates and on other matters of interest to the House will be presented at the first meeting in New York

AUDITORS REPORT

March 15 1957

The Board of Trustees
American Medical Association

We have examined the statement of assets and liabilities of the American Medical Association as of Dec 31 1956, and the related statement of income and capital for the year then ended Our examination was made in accordance with generally accepted auditing standards and accordingly included such tests of the accounting records and such other auditing procedures as we considered necessary in the circumstances

In our opinion the accompanying statement of assets and liabilities and statement of income and capital present fairly the financial position of the American Medical Association at Dec 31 1956 and the results of its operations for the year then ended in conformity with generally accepted accounting principles applied on a basis consistent with that of the preceding year

REPORT OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

To the Members of the House of Delegates of the American Medical Association

The following report of the Council on Medical Education and Hospitals is respectfully submitted

Recommendation for Adoption of the Document Functions and Structure of a Modern Medical School to Replace the Essentials of an Acceptable Medical School

Following a year of careful study the Council on Medical Education and Hospitals in collaboration with the Association of American Medical Colleges has completely revised the Essentials of an Acceptable Medical School initially approved by the House of Delegates in 1910 and most recently revised in 1951 The new document represents the current general philosophy and concepts of these two organizations and has been developed as a basic guide It has been endorsed by the Executive Council of the Association of American Medical Colleges and by the Liaison Committee on Medical Education as well as by the Council on Medical Education and Hospitals The Council has voted adoption of the document entitled Functions and Structure of a Modern Medical School to replace the present Essentials of an Acceptable Medical School, and authorized its presentation to the House of Delegates with the recommendation that it be given official endorsement (See Appendix A)

Recommendation for Approval of Publication of Guides and Basic Principles of Postgraduate Medical Education'

During the past year the Ad Hoc Advisory Committee on Postgraduate Medical Education met on several occasions to consider recommendations for the future functions of the Council in this field The Committee assumed as one of its major responsibilities the task of preparing a statement of the Objectives and Basic Principles of Postgraduate Medical Education Programs as a guide for the information of individuals and organizations conducting or planning to conduct, activities in this field Following detailed study and numerous revisions, this statement was submitted to the Council on Medical Education and Hospitals for consideration The Council has voted to endorse the statement on Objectives and Basic Principles of Postgraduate Medical Education and refers it to the House of Delegates for consideration with the recommendation for its approval and subsequent publication (Appendix B)

Organization of Committee to Study Best Background Preparation for General Practice

At its meeting on Dec 14, 1956, the Executive Committee of the Board of Trustees voted that the Council on Medical Education and Hospitals should address itself to instructions 3 and 4 of the report of the Committee on Medical Practice made to the House of Delegates in Seattle (November, 1956) Therefore a committee with representation from the Council on Medical Education and Hospitals the Association of American Medical Colleges and the American Academy of General Practice has been established to proceed to objectively analyze and make recommendations as to the best background preparations today for general practice Representatives of the specialty areas will be added to the committee during the course of its deliberations

The initial meeting of this committee was held in January, at which time it was agreed to consider the following questions 1 What is general practice? 2 Is what is defined as general practice of lasting value to the health care of the United States public? 3 What preparation is needed for this type of practice? 4 How can this preparation best be offered?

The committee adopted a basic working definition of general practice and appointed three subcommittees to carefully consider and report on the following facets of the problem (*a*) prepare a descriptive clarification of the working definition of general practice (*b*) prepare a statement developing the thesis as to whether the kind of physician outlined in the working definition is of lasting value to the health care of the United States public, and (*c*) prepare a report on suggestions as to the preparation needed as background for general practice in keeping with the implications of the working definition

The reports of the studies of this committee and its subcommittees together with its recommendations will be submitted in due course

Inhalation Therapy

In June 1956, the House of Delegates approved in principle, the establishment of educational programs for inhalation therapy technicians and requested the Council to study the development of criteria for such training The advice of several national professional organizations has been sought Recently appointed committees on inhalation therapy of the American Society of Anesthesiologists, Inc , and the American College of Chest Physicians plan to meet jointly in June 1957 Pending the completion of these studies the Council deferred action in view of the need for further definition and study of inhalation therapy and encourages the integration and coordination of such specialized training with existing closely related education programs

The Straight Internship

In view of the resolutions submitted at the June 1956 Annual Session of the House of Delegates in regard to rotating vs straight internship the Council is making further studies in this field Although a definitive recommendation is not being submitted at this time, the Council believes that the House of Delegates should be apprised of the studies under way and should have an opportunity to evaluate the opinions of responsible hospital administrators and members of the profession as to the pros and cons of straight and rotating internship as well as their attitudes in regard to any inflexible ruling concerning the elimination of either type (Appendix C)

Suggested Change in Name of the Council to Council on Medical Education

With the establishment of the Joint Commission on Accreditation of Hospitals on Dec 15, 1951, the field of accrediting hospitals was completely taken over by this body During its first five years of activity, members of the Field Staff of the Council on Medical Education and Hospitals functioned in the dual capacity of evaluation of hospitals for accreditation by the Joint Commission and in evaluation of graduate education (internship and residencies) for the Council The report of the Stover Committee to the House of Delegates in June, 1956 recommended that the Commission should employ its own surveyors, since it is not concerned with internship and residency approval and that the American Medical Association continue to survey such graduate medical education programs through the Council on Medical Education and Hospitals This recommendation was adopted by the House of Delegates and on Jan 1, 1957, the Council reduced its Field Staff accordingly as it discontinued evaluation of hospitals for accreditation by the Joint Commission

During the June, 1954 meeting in San Francisco the Board of Trustees submitted a statement concerned with the discontinuation of hospital registration by the Council on Medical Education and Hospitals which was approved by the House of Delegates The Council on Medical Education and Hospitals compiled its last census on Hospital Service in the United States in 1954 and hospital registration has subsequently been taken over by the American Hospital Association At the time the Council discontinued compilation of annual hospital registration information its Essentials of a Registered Hospital were declared no longer in effect

The Council on Medical Education and Hospitals therefore has no function relative to accreditation or registration of hospitals as such It is however vitally concerned with the internship program and is the sole agency responsible for its evaluation as an educational and training experience It is also vitally concerned with residency education and training which is currently evaluated through residency review and conference committees These committees represent conjoint efforts on the part of the Council the specialty boards, and/or other organizations concerned with graduate education and training The Council is also actively engaged in the long-range study of postgraduate medical education and the role of medical schools, hospitals medical societies and other agencies in such activities

Since the interests and activities of the Council are primarily focused on evaluation and approval of undergraduate, graduate, and postgraduate medical education, and since it plays no direct role in hospital accreditation or registration per se, the name Council on Medical Education and Hospitals' is a misnomer and should be changed to the Council on Medical Education in conformance to its true functions The Council recommends to the House of Delegates that the words and Hospitals' be deleted and that its name be changed to Council on Medical Education

APPENDIX A

FUNCTIONS AND STRUCTURE OF A MODERN MEDICAL SCHOOL

I INTRODUCTION

This statement has been prepared in collaboration with the Association of American Medical Colleges and represents the general concepts of that organization as well as the Council on Medical Education and Hospitals of the American Medical Association It is intended that this material be used as a guide with the hope that it may assist in attaining medical education of ever higher standards Experience indicates that these are best nurtured in an environment in which there is not excessive concern with standardization The concepts expressed here will serve as general but not specific criteria in the medical school accreditation program However it is urged that this document not be interpreted as an obstacle to soundly conceived experimentation in medical education

Published originally as Essentials of an Acceptable Medical School, and approved by the House of Delegates of the American Medical Association June 1910 and revised April, 1913, March and October, 1927 June 1933, June, 1934, August, 1936 June 1938 December, 1945, and December, 1951

II THE RESPONSIBILITIES AND OBJECTIVES OF A MEDICAL SCHOOL

As an institution of higher education a medical school has three inherent responsibilities which are so closely related as to be inseparable

1 *A medical school should provide for its undergraduate students the opportunity to acquire a sound, basic education in medicine and should foster the development of lifelong habits of scholarship*

2 *A medical school should contribute to the advancement of knowledge through research*

3 *A medical school should contribute to the development of teachers, investigators and practitioners through programs of graduate education including residency training*

By virtue of its university orientation or as a result of the clinical facilities and personnel available, a medical school should assume additional responsibilities such as those listed below to the degree that its resources permit without weakening its basic program

1 Leadership in the development of adequate opportunities for the continuing education of practicing physicians

2 Professional service to patients primarily to fulfill its educational and research obligations

3 Participation in the educational programs of other professions in the health field such as dentistry, nursing, and pharmacy, as well as in selected areas of the general university program

4 Training of technical personnel in paramedical fields

A medical school should develop a clear definition of its total objectives, appropriate to the needs of the community it is designed to serve and the resources at its disposal When objectives are clearly defined, they should be made familiar to faculty and students alike, so that efforts of all will be directed toward their achievement

A statement of The Objectives of Undergraduate Medical Education has been prepared by the Association of American Medical Colleges It is believed that this can well serve as the basis for a definition of this portion of the over-all objectives of a medical school and is reproduced in part below The full statement can be found in the *Journal of Medical Education* (28 57-59 [March] 1953)

Undergraduate medical education must provide a solid foundation for the future physician s development It should not aim at presenting the complete detailed, systematic body of knowledge concerning each and every medical and related discipline Rather, it must provide the setting in which the student can learn fundamental principles applicable to the whole body of medical knowledge establish habits of reasoned and critical judgment of evidence and experience, and develop an ability to use these principles and judgments wisely in solving problems of health and disease

Undergraduate medical education cannot achieve these aims if the student is relegated to a passive role It must provide incentive for active learning on the part of the student This can best be done by giving him definite responsibility in real, day-to day problems of health and disease This responsibility must, of course, be carefully graded to the student s ability and experience and must be exercised under careful guidance by the faculty

Given incentive to learn and guidance toward the grasp of principles, with the problems of health and disease as a frame of reference the student will build the necessary foundation for his career in medicine, be it practice (general or limited) teaching, research or administration

'In working toward this fundamental objective undergraduate medical schools must strive to help the student to acquire basic professional knowledge, establish essential habits, attain clinical and social skills necessary to the best utilization of that knowledge, and develop those basic intellectual attitudes, and ethical or moral principles which are essential if he is to gain and maintain the confidence and trust of those whom he treats the respect of those with whom he works and the support of the community in which he lives

These aims are obviously not distinctly separable, but are mutually interdependent All together they summarize the desirable characteristics of the responsible professional person medical education is attempting to produce

III ORGANIZATION AND ADMINISTRATION

A *Governing Body*—A medical school should be incorporated as a nonprofit institution, if possible as a part of a university, since a university can so well provide the milieu and support required by a modern medical school

If not a component of a university, a medical school should have a board of trustees composed like that of a university of public spirited men or women having no financial interest in the operation of the school or its associated hospitals The trustees should serve for fairly long and overlapping terms

Officers and faculty of the school should be appointed by the board of trustees In keeping with generally accepted principles of administration, it is usually not desirable for a member of the board of trustees to serve simultaneously as an administrator or a member of the faculty of the medical school

The manner in which the medical school is expected to conduct its affairs, including the responsibilities and privileges of administrative officers, faculty, and students should be clearly indicated in by-laws approved for the medical school itself or adequately presented in the by-laws of the parent university

B *Administrative Officers of the Medical School*—There should be competent supervision of the medical school by the dean or other executive officer who, by training and experience is qualified to provide leadership in interpreting high standards in medical education, and who has sufficient authority to implement such standards The dean should have the respect and support of the faculty and ready access to the university president and other officials The establishment and maintenance of a congenial and productive relationship with the local medical profession is desirable and important to the school and the profession It can be best assured through discussions of mutual problems by representatives of the school and practicing profession

Because of the diverse and heavy responsibilities placed upon the dean or executive officer, assistance by suitably qualified persons should be provided In many medical schools, for example, there is an assistant dean who devotes major attention to student affairs and another assistant for administering the postgraduate program In the conduct of the fiscal affairs of the school, the dean should have the assistance of a capable business officer

C *Faculty Organization*—The faculty should be organized into suitable departments representing the major basic science and clinical fields It is to be noted that this is primarily an administrative convenience it should not form the sole basis for structuring the curriculum Each such department should have a voice through appropriate committees of the faculty, in the administration of the academic affairs of the school Foremost among these should be an executive committee of the faculty composed primarily of the responsible administrative officials and the chairmen of those departments which have a major role in the educational program Usually these are Anatomy, Physiology, Biochemistry, Microbiology, Pharmacology, Pathology Medicine Surgery, Pediatrics, Obstetrics Gynecology, Psychiatry, and *Preventive Medicine and Public Health* This commonly utilized pattern allows for balance between basic science and clinical viewpoints in the committee's major function of determining with the dean, medical school policies for consideration, where indicated, by higher university authority

There should be such committees of the faculty as admissions promotions curriculum, postgraduate medical education, library, and others needed to serve the welfare of the school

The entire faculty should meet one or more times annually to provide an opportunity for all faculty members to become acquainted with and to discuss medical school policies and practices

Nominations for faculty appointments should originate in the faculty under the leadership of the dean Commonly, nominations for appointments at the lower academic ranks are made by the head of the department concerned, after thorough discussions of the nominees by the entire department At the professorial and the associate professorial levels this procedure may be profitably supplemented or supplanted by the appointment of a nominating committee composed of members of several departments, whose standing and judgment are generally unquestioned Recommendations are made to the faculty executive committee and dean who in turn, recommend to the president and board of trustees through established administrative channels

D *Finances*—Experience has established that a medical school cannot successfully carry out its many activities solely on the income derived from student fees Furthermore, certain of these activities are not directed primarily to the education of the medical student and he should not be expected to support them To adequately fulfill its obligation, a medical school should have other substantial sources of revenue

Each department within the school should prepare its budget in consultation with the dean, who is ultimately responsible for the total budget and its presentation to the proper authority

IV FACULTY

The school should have a competent staff with demonstrated interest and ability in teaching and research Such dual activity by the faculty is most likely to provide the educational milieu appropriate in a modern medical school as well as best carry out its objectives and responsibilities

Reasonable security of tenure and possibility of advancement should be assured in order that the personnel of the faculty may have adequate stability Compensation of full time members of the faculty should be sufficient to enable them to support themselves and their families

The number of instructors in each basic science and clinical department should be sufficient to meet the requirements of a modern medical educational program as well as allow adequate time for research by each instructor Full time teacher student ratios may vary widely depending on the course content educational methods, research activities, the availability of competent part time or voluntary staff and other factors Recognition of the values of intimate teacher-student relationships and widespread use of methods favoring the active role of the student in his own education have decreased dependence on didactic exercises Increasing use has also been made of interdepartmental teaching These factors have tended to increase the relative size of the instructional staff

The faculty personnel in the basic science disciplines should be almost entirely on a full time basis In the major clinical areas of medicine surgery, pediatrics, psychiatry obstetrics and gynecology, there should be a nucleus of full time instructors who have as their major responsibility the planning and supervision of the department's educational program and the conduct of research

V STUDENTS

The admission of students to a medical school should be the responsibility of a committee of the faculty Decisions regarding admission should be based not only on satisfactory prior scholastic accomplishment but also on such factors as personality and emotional characteristics, motivation, industry resourcefulness, and health Evaluation of these factors should be developed through personal interviews college records of academic and nonacademic activities results of medical college admissions tests, and pertinent letters of recommendation All records dealing with admissions should be carefully filed and procedures periodically reviewed in a search for better methods

At least three years of college education is required for most students and four years is recommended as a preparation for medical study Only rarely and under exceptional circumstances will a medical school be justified in admitting a superior student after two years of college study The National Committee of Regional Accrediting Agencies maintains a listing [1] of institutions of higher education which have been found to offer commendable educational programs Prospective medical students should acquire their preparatory education at a college of arts and sciences so listed and a medical school admissions committee should scrutinize with particular care the qualifications of applicants whose preparatory study has been done at other institutions

Because basic knowledge of biology, physics, inorganic and organic chemistry and human behavior are the foundation stones of medicine, adequate college courses in these subjects as well as demonstrated competence in English, should be required It is important that a medical college restrict its admission requirements to this minimum so that a college student preparing for the study of medicine will have the opportunity to acquire a broad liberal education or to study a specific field in depth according to individual interest and ability The complexity of modern medicine can be best served by physicians who in composite represent a variety of backgrounds in education and experience

---

[1] A copy can be obtained by addressing the National Commission on Accrediting, 1785 Massachusetts Ave N W, Washington 6, D C

Advanced standing may be granted to students for work done in other medical schools, but only when a student's previous work is qualitatively and quantitatively equivalent to that required of regularly enrolled students as officially verified by correspondence with the school previously attended. Because of the diversity and greater integration of the total curriculum transfers are becoming increasingly difficult but usually are least disruptive of the student's education at the end of the second year.

The number of students who can have an adequate education in a medical school is related to the laboratory and hospital facilities available and to the size and qualifications of the teaching staff (see also IV Faculty). A close personal contact between students and members of the teaching staff results in a quality of educational experience that is not possible in an institution where the number of students is excessive in relation to the staff and facilities.

There should be a system of student records showing conveniently and in detail the admissions credentials as well as the grades or other records of performance in the school, by means of which an exact knowledge can be obtained regarding each student's work and qualifications. Qualitative evaluations of each student by instructors should be included in the student records.

An adequate provision for student counseling should be in effect. Many schools have an assistant responsible to the dean for such counseling.

There should be an active student health service providing for periodic medical examination and medical care for the student body. This is important not only in the maintenance of student health but also because of its inherent educational values.

VI FACILITIES

A medical school should own or enjoy the assured use of buildings and equipment adequate quantitatively and qualitatively to provide an environment most conducive to productivity of faculty and students in the fulfillment of the total objectives of the school. If possible all of the basic medical sciences should be housed in a building which adjoins in some manner the clinical facilities so as to promote cooperative teaching efforts and allow all departments ready access to clinical material.

A well maintained and catalogued medical library that can be used conveniently and effectively by both students and faculty is essential to a modern medical school. A trained librarian with experience in medical library work should be employed to supervise the development and operation of the library with the advice and assistance of an active representative committee of the faculty. The library should receive regularly the leading medical periodicals, the current numbers of which should be readily accessible. Adequate arrangements should be made by the librarian and the faculty to instruct all students in the use of the library at the beginning of their medical studies.

The school should own or have the unquestioned right to appoint the attending staff of a general hospital for clinical teaching. In the event that a medical school depends for clinical teaching on an independent hospital, it is essential that the clinical teachers, either on nomination by the school or by agreement in conference between school and hospital, be appointed by the hospital trustees to appropriate positions on the hospital staff. The teaching hospitals should be either adjoining or in close proximity to the school and should provide sufficient patients to permit students individually to observe, work up, and study the progress of the common variety of medical and surgical cases as well as a fair number of patients in each of the other major specialties.

There should be a sufficient number of patients so that each student on a hospital clerkship can be assigned that number of new cases of teaching value each week for thorough study that the faculty judges to be of maximum educational value. For example, this may be two new patients a week in one department or five new cases weekly in another, depending upon the orientation objectives and teaching program of the department concerned. Therefore, no fixed number of hospital beds or patients per student can be established because of the variables involved. Medical education should emphasize intensive long term study by each student of relatively fewer patients rather than superficial observation of many patients.

The school should own or have unquestioned use of well ordered facilities for the diagnosis, treatment and follow-up of ambulatory patients. The attending staff should be drawn from the faculty including those of senior rank. The number of new cases per day available to each student serving an outpatient clerkship should be compatible with the educational objectives and teaching program of the department as well as the school.

There should be sufficient offices, laboratories, and conference rooms as a part of or conveniently close to the hospital and outpatient clinical facilities to meet the needs of faculty and students. The hospital floors should provide adequate space and facilities for student clerks to study their patients.

VII EDUCATIONAL PROGRAM

Before the curriculum, methods and details of an educational program can be decided the objectives of the program should be formulated.

The objectives should clearly indicate that an undergraduate medical education provides merely a sound foundation for further education during the internship and residency periods, as well as throughout professional life. Four years of education in medical school is not by itself sufficient to prepare a physician for practice today. In fact, the yearly advances in medicine demand that each physician continue his education throughout his career. It is also obvious that no physician can master the whole spectrum of medical knowledge.

No rigid curriculum can be prescribed for accomplishing the objectives of medical education. On the contrary, it is the responsibility of the faculty of each school continually to re-evaluate its curriculum and to provide in accordance with its own particular setting and in recognition of advances in science a sound and well-integrated educational program. Each school should utilize those methods and approaches that the particular interests and abilities of the faculty indicate would provide the most effective education in the framework of the available facilities. The traditionally separate disciplines are finding rewarding educational and research results in working together cooperatively.

Through the various educational methods and to the extent deemed best by the faculty to accomplish the objectives of medical education, each medical school should offer education in the following subjects during the four year curriculum:

Human Anatomy, Biochemistry, Physiology, Microbiology, Pharmacology, Pathology, Clinical Laboratory Diagnosis, Physical Diagnosis, Internal Medicine, Pediatrics, Obstetrics and Gynecology, Preventive Medicine and Public Health, Psychiatry, Radiology, and Surgery. Specialty areas in medicine and surgery are best integrated in the teaching of the major disciplines. Consideration of social, emotional and environmental factors in health and disease is properly the responsibility of all clinical departments. Medical ethics, legal medicine, biostatistics and medical genetics should be included in the educational program.

The traditional emphasis on lectures, demonstrations and amphitheater clinics in which the role of the student is passive has shifted to greater use of individual student and small group projects, conferences, seminars and the "case method" of education, in all of which the student actively participates in his own education. The allotment of some unscheduled student time in the weekly program to allow for reading, research or other independent pursuits is desirable.

In the clinical years particularly, there is no substitute for the "case method" of clinical education, in which individual students work up individual patients under guidance in the hospital wards and in outpatient clinics. Such assignments should occupy most of the time and energy of third and fourth year medical students. The student should be encouraged to feel a genuine responsibility as part of a team of physicians studying the patient, and not as a classroom student with prescribed hours of work. The student's work-up of each case including progress notes should become part of the hospital's permanent record of the case. Such case studies should serve as the point of departure for informal conferences, rounds and reading. Lectures and other didactic exercises cannot replace though they may supplement bedside learning.

VIII ACCREDITATION OF MEDICAL SCHOOLS

The American Medical Association through its Council on Medical Education and Hospitals and the Association of American Medical Colleges through its Executive Council serve as the recognized accrediting agencies for medical schools Though retaining their individual identities, both groups work very closely in this activity through the Liaison Committee on Medical Education To be accredited a medical school must be considered approved by the Council on Medical Education and Hospitals and offered membership in the Association of American Medical Colleges This is granted on the finding of a sound educational program as a result of a survey conducted jointly by both organizations

It is the intent that newly developing medical schools should be surveyed during each of the first four years of active existence Provisional accreditation is granted when the program warrants, for the first two years of the curriculum and definitive action is taken during the implementation of the fourth year of the curriculum

Existing medical schools are surveyed at regular intervals Every attempt is made to fulfill requests for interim surveys as a consultant service to the medical schools

A medical school to be surveyed is requested to provide basic information on forms forwarded in advance After careful study of this material, the survey team of three or four members visits the medical school for three to five days On completion of its visit the survey team confers with the responsible administrative officials of the medical school and its parent university, indicating to them the nature of the major findings and recommendations A complete written report is prepared and considered separately by the Council on Medical Education and Hospitals and the Executive Council of the Association of American Medical Colleges and then jointly by the Liaison Committee on Medical Education The action of each group and the complete report is then transmitted to the medical school dean and university president

Application for and further information concerning this process can be obtained from the Secretary, Council on Medical Education and Hospitals, American Medical Association, 535 N Dearborn St, Chicago 10, or the Secretary, Association of American Medical Colleges, 2530 Ridge Ave, Evanston, Ill

APPENDIX B

A Guide Regarding Objectives and Basic Principles of Postgraduate Medical Education Programs

PREFACE

Physicians have become increasingly concerned with their need for effective continuing educational opportunities in order that the advances in medical knowledge may be applied in practice with as little delay as possible Though this need has been clearly recognized there has been a lack of basic guidance regarding what educational approaches would be most useful Postgraduate medical education poses a variety of problems Although a few are unique, many of the problems are similar to those that confronted other phases of medical education earlier in this century

In order to best explore the problems and useful approaches to their solution, the Council on Medical Education and Hospitals of the American Medical Association decided that it should have the advice of leaders in the profession having a diversity of backgrounds and viewpoints in practice and in medical education Accordingly, early in 1956, the Council sought and obtained from the Board of Trustees of the American Medical Association authorization to appoint an Ad Hoc Advisory Committee on Postgraduate Medical Education This committee which began its task in April, 1956, and is still at work, is composed of the following members

Dr Clarence E de la Chapelle Professor of Medicine and Associate Dean New York University Post Graduate Medical School
Dr John Conlin Medical Director Boston City Hospital
Dr Mahlon Delp Professor of Medicine and Chairman of the Department of Postgraduate Medicine University of Kansas School of Medicine
Dr William B Hildebrand general practitioner and Former President American Academy of General Practice
Dr James T Howell Assistant Medical Director Henry Ford Hospital representing Dr Edwin Crosby American Hospital Association
Dr Harold Jeghers Professor and Director of the Department of Medicine Seton Hall University School of Medicine
Dr Matthew R Kinde Director of Division of Medicine and Public Health W K Kellogg Foundation
Dr Samuel Proger Professor and Chairman of the Department of Medicine Tufts University School of Medicine and Physician in Chief New England Medical Center
Dr John Sheldon Professor of Medicine and Director Department of Post graduate Medicine University of Michigan School of Medicine
Dr Cassius J Van Slyke Associate Director National Institutes of Health
Dr Edward L Turner Secretary Council on Medical Education and Hospitals American Medical Association
Dr John C Leonard Chairman of the Committee Director of Medical Education Hartford Hospital

Dr Glen R Shepherd Assistant Secretary of the Council, is serving as staff for the committee The committee was asked to examine postgraduate medical education in its broadest aspects and to recommend to the Council a course of action that the American Medical Association could take that would be of assistance in increasing the educational stature of this field At the outset of the committee s deliberations, it became apparent that a basic guide needed to be formulated and published by the Council, a guide that would be applicable to courses as well as to other approaches such as community hospital–medical school cooperative efforts The following material is the product of this part of the committee s work

It is very gratifying to report that from its beginning the committee has pursued its task with extraordinary vigor and enthusiasm bespeaking the importance of the subject of its study All members of the committee have participated actively in its deliberations, and each member made a significant contribution to this outcome of the committee s work

The Objectives and Basic Principles of Postgraduate Medical Education formulated by the committee and endorsed by the Council is a major contribution to an initial clarification of goals and guiding principles in this continuing phase of medical education On behalf of the Council it is my pleasure to express deep appreciation to the members of the committee for the important work they have completed to date and to commend this document to all concerned for thoughtful study and active attention

H G Weiskotten, M D, Chairman
Council on Medical Education and Hospitals
American Medical Association

INTRODUCTION

The purpose of this publication is the presentation of objectives and basic principles of postgraduate medical education programs for the guidance of those active in this field as well as for those desiring to initiate courses and other programs for the continuing education of physicians

Vital new discoveries are of little immediate use against human disease until physicians in practice learn about them Regardless of how well prepared a physician may be at the time of entering practice the adequate knowledge of yesterday is not fully adequate today How best to meet this educational challenge is the broad problem of continuing postgraduate medical education

The American Medical Association and its Council on Medical Education and Hospitals have become increasingly concerned with the educational activities and needs in this postgraduate phase of medical education It is apparent that formal courses are only a part of the educationally significant programs in this field

In 1952 the Council initiated a study of the field of postgraduate medical education, the results of which were reported by Dr Douglas Vollan in The Journal in 1955 [1]

---

1 Vollan, D Postgraduate Medical Education in the United States J A M A **157**:703-708 (Feb 26) 1955, ibid **157**:912-920 (March 12) 1955, ibid **157**:1119-1125 (March 26) 1955, ibid **157**:1302-1309 (April 9) 1955 ibid **157**:1492-1498 (April 23) 1955, ibid **158**:39-43 (May 7) 1955 ibid **158**:184-187 (May 21) 1955 ibid **158**:395 399 (June 4) 1955

A physician adds to his knowledge by participation in the following activities (1) reading of the medical literature (2) consultations with colleagues (3) hospital staff meetings and conferences (4) local state, and national meetings of general and specialty medical societies, (5) formal postgraduate courses and (6) regional hospital–medical school educational programs

The educational implications of reading the medical literature consulting with colleagues and medical society meetings are significant but they are under the direct control of the individual physician The enormous and increasing bulk of medical literature on even relatively restricted subjects makes difficult the maintaining of a current knowledge by this means alone The routine medical society meetings are often of necessity not primarily educational

Postgraduate programs by hospitals medical schools, and medical societies on the other hand, involve groups of people and educational techniques having close analogies with undergraduate and graduate medical education All three phases of medical education may involve the same educators It is with such programs—formal courses and regional hospital–medical school cooperative educational efforts—that the Council on Medical Education and Hospitals hopes to be of assistance

The basic problems confronting those who plan programs for the continuing education of physicians are analogous to the problems that faced those responsible for undergraduate medical education fifty years ago and that concerned graduate medical education more recently These problems include (1) a lack of clear definition of objectives (2) a wide range in the educational value of the courses and other programs offered (3) insufficient opportunities for physicians to participate in educationally sound programs (4) difficulties in financing and (5) lack of national guidance and inadequate sharing of experience for those desiring to establish or improve postgraduate medical education programs

The Ad Hoc Advisory Committee on Postgraduate Medical Education described in the Preface has prepared and the Council endorses the Objectives and Basic Principles for Postgraduate Medical Education Programs as set forth in the following pages These principles are applicable as the explanatory notes suggest to any concerted educational effort involving physicians This publication is an initial step in a long-range program that the Council will pursue to assist in the further development of postgraduate medical education After a suitable period following publication of this guide, a continuing appraisal of postgraduate programs may be initiated

OBJECTIVES

The ultimate aim of postgraduate medical education is to make it possible for each physician to use in his practice the modern medical knowledge that continuously becomes available Adequate professional growth ensues through the participation of each physician in suitable programs of continuing education in addition to his own experience and reading

Postgraduate educational programs should as a result of current advances in the basic science and clinical fields favorably augment and modify an adequate initial education These programs should make possible the acquisition of such new skills in the field of original competence as scientific advances require All continuing education should strengthen the habits of critical inquiry and balanced judgment that denote the truly professional and scientific man

BASIC PRINCIPLES FOR POSTGRADUATE MEDICAL EDUCATION PROGRAMS

1 There should be ADMINISTRATION of the postgraduate program by a responsible person having the respect and support of the professional staff of the organization or institution, an administration having as its goal an educational program in the highest interest of the medical profession, as epitomized in the Objectives previously stated There should be continuity of administration, evidence of careful advance planning of the program, and a suitable voice by the teaching staff in the postgraduate program

The majority of medical schools express a sense of responsibility for the continuing education of physicians To implement their programs, some schools have appointed assistant deans for postgraduate medical education or directors of departments, sections or committees charged with over-all planning and coordination of such continuation education [2]

The assistant dean or director has such responsibilities, in consultation with the dean and/or executive committee of the faculty as determining the specific needs and desires of the profession in the region for the subjects of courses and other programs, stimulating the faculty to plan programs well in advance, making certain that the facilities needed will be available at the time scheduled, supervising adequate enrollment records in courses, serving as liaison with local and national medical societies, and otherwise coordinating the resources of the school for their most effective use in the postgraduate program undertaken Continuous administrative supervision of the postgraduate program by a responsible person results in a higher quality educational experience than is otherwise possible

Hospitals have found effective the designation of a director of medical education to be concerned with supervision of internship and residency programs Such an individual could become the executive officer of the postgraduate program of the hospital serving in a similar capacity and for similar purposes as the director of the postgraduate program in a medical school

Any cooperative educational effort between a regional hospital and a medical school should have the understanding and approval of the medical staff, administrator and trustees of the hospital as well as the understanding and approbation of the dean and the executive committee of the faculty of the medical school

Where a hospital or medical school is nearby medical societies and other organizations concerned with cosponsorship of educational programs for physicians may find it best to work cooperatively with the hospital or medical school as the actual location of the program because of the personnel and facilities uniquely available there The advantages of administrative continuity of such relationships by a medical society or other organization are at least partially as compelling as is such continuity of administration for hospitals and medical schools

2 The BUDGET should be adequate to the educational program undertaken and to its continuing improvement

Sole dependence upon tuition fees tends to restrict unduly the quality of postgraduate courses In general therefore, support for such activities should not be confined to anticipated income from tuition, and other financial resources should be available

The support of adequate postgraduate courses and regional cooperative programs necessitates the furnishing of faculty personnel, certain special teaching facilities for physicians attending courses, transportation factors involved in regional and circuit programs, honoraria, and administration the total support of which is in excess of tuition income alone It is important that the faculty personnel be sufficient to continue to provide an adequate program of undergraduate medical education when the postgraduate program is in effect

Hospitals expend funds for the salaries of directors of medical education when they are full time for travel expenses of residents and interns to the medical school when that is a part of the program, for special facilities such as adequate library, conference rooms and audio-visual equipment needed in the various programs and for assistants

3 The TEACHING STAFF should consist of physicians and their associates of proven ability, training, and experience with an interest in and dedication to the development of carefully planned educational programs in the best current intellectual and professional interest of the participating physicians

There should be an adequate number of instructors for each program to permit the use of the more effective participative methods of education (see Principle 6) In the other phases of medical education and in other fields of education, the number of students per teacher becomes much smaller as education becomes more advanced This would seem to have significant implications in postgraduate medical education

---

[2] Fifty-sixth Annual Report on Medical Education in the United States and Canada by the Council on Medical Education and Hospitals of the American Medical Association J A M A **161**:1666-1667 (Aug 25) 1956

Instructors participating in any course or other educational program should be capable of providing explanation of the basic science mechanisms of health and disease and their clinical applications in the prevention, diagnosis and treatment of disease The essence of professional knowledge as compared to purely vocational, is understanding of the basic sciences to provide a know-why as well as a 'know-how' of the practice of medicine

The resident staff of a hospital, and particularly of a regional hospital, may form a valuable part of the teaching personnel of a postgraduate program It is generally considered that the attending staff of a hospital in its contacts with interns and residents in an approved program stimulates and educates the resident staff It is also true that the intern and resident staff coming recently from the research and teaching ferment of a medical center can stimulate and inform the attending staff of a community hospital Such a two way exchange of ideas and mutual ignition of curiosity is implicit in any effective graduate educational program It is at times difficult to delineate clearly whether the graduate or postgraduate medical education implications are the greatest in various features of some of the existing and experimental ventures between regional hospitals and medical schools The benefit to the attending staff is directly related to its wholehearted participation in the various conferences, ward rounds, and other activities of the program

4 The CURRICULUM of any postgraduate medical education program should be the result of thoughtful planning well in advance of the date scheduled for the beginning of the program

In the case of courses, this advance planning should include selection of the general subject(s), the hour by hour schedule of topics and activities, the assignments of these to specific members of the teaching staff, and the selection of the appropriate methods of education

The value of a postgraduate program depends to a considerable extent on the amount of thoughtful planning that occurred months in advance of its beginning Even continuous cooperative efforts between hospitals and medical schools require periodic self-appraisal of the purposes, the methods of education, and the teaching staff Advances in medicine are occurring so rapidly that no course or other program should be repeated annually without such restudy

Thoughtful planning also means that the content of courses and other programs should be based upon the demonstrated needs and wishes of the physicians of the region, as well as upon advances in medicine The means of ascertaining the needs and wishes of physicians will vary Of great assistance is a close and cordial liaison among medical societies, medical schools, and hospitals of the region

Attention to the newer knowledge of the basic mechanisms of disease and of treatment should be a part of postgraduate programs along with the more immediately applicable information

It is desirable that more institutions and organizations responsible for courses and for regional hospital programs design their content so that advances in all the major areas of medicine can be covered every four to five years Cooperative planning in each region would be of assistance in this respect

Postgraduate courses which by their duration and nature cannot fully prepare any physician for entering the practice of a specialty should be so structured in all subjects and especially those of the surgical specialties that the physicians participating will fully realize the dangers of using limited knowledge without restriction and without consultation It is because of the hazards involved that postgraduate courses on surgical techniques often are limited to enrollment of those who have had adequate basic education in surgery The longer period of study needed for surgical practice is best spent in approved programs of graduate medical education rather than in short postgraduate courses There is much information regarding diagnosis, the indications and contraindications for surgery, the basic science involved in such therapy, and the expected outcome of various surgical procedures that should be made available to all physicians

5 There should be available FACILITIES that encourage participative methods of education Though lectures by professionally well qualified speakers are a means whereby physicians obtain information, it is felt that such a method of education cannot alone provide an adequate postgraduate program in the context of modern education The facilities mentioned above should include the availability, when appropriate to the content of the program, of patients and their case records and other necessary records such as roentgenograms, electrocardiograms, surgical pathology tissues and/or reports, laboratories, library, conference rooms, classrooms, and audiovisual aids, all adequate for and suitable to the specific program

The facilities stipulated are those found in hospitals and medical schools Short courses sponsored or cosponsored by other organizations could well cooperate with nearby hospitals and/or medical schools in order to utilize their facilities

A hotel ballroom or a lecture hall used alone and isolated from a hospital or medical center does not provide those essential facilities needed in modern medical education, whether it be for students working toward the M D degree or for physicians in practice enrolled in a course or participating in other primarily educational programs

6 The EDUCATIONAL METHODS should include more than a series of lectures or panel discussions in which the physicians are primarily passive recipients Methods requiring active participation include live clinics and bedside rounds, seminars, open question periods, laboratory work, and study of patients under supervision

There is ample evidence in the undergraduate and graduate phases of medical education that overemphasis on purely didactic methods provides an educational program that is inferior to one requiring active participation

It should be noted that any potentially active method of education, such as ward rounds can become a purely passive exercise if a group is too large e g , bedside groups of 6 to 8 physicians would be likely to encourage a participation of each, while bedside groups of more than 10 might easily consist of standing lectures

Strictly as aids to education rather than as the sole method (except in the case of home study courses by television or audiovisual kits), the use of suitable colored slides and motion pictures, models, and color television is encouraged However, the import of television to medical education is still in the exploratory and experimental phase

One of the major problems in postgraduate medical education is lack of concern for the methods of education used This is particularly true of courses, according to a study of the 1955-1956 offerings made by the Council on Medical Education and Hospitals In the Annual Report on Medical Education in the United States and Canada,[3] the section on postgraduate courses summarized this data as follows The more active participative methods of instruction were used in 84 7% of the postgraduate courses offered by hospitals, 59% of the courses offered by medical schools, and in only 22% of the courses offered by medical societies

When lectures are utilized, it is valuable also to conduct group discussions and question-answer sessions as follow through techniques Similarly, though appropriate audiovisual aids are of assistance they should be simply a part and integrated into a planned educational program Catalogues containing lists of suitable motion pictures and their sources are available from the Director of Medical Motion Pictures and Television, American Medical Association, 535 N Dearborn St, Chicago 10

Surgical galleries and demonstration of surgical techniques to large groups of passive spectators leave much to be desired and also fall short of fulfilling educational needs It is conjectural whether even skilled surgeons can add techniques to their armamentaria simply by watching other surgeons at a distance It would seem that some modification of the medical traineeship or residency applicable for the postgraduate student could be developed Thus surgeons desiring to learn a new procedure might have opportunities to perform it repeatedly under the supervision of its originator or his protege in a manner providing a significant educational experience

---

[3] Fifty-sixth Annual Report on Medical Education in the United States and Canada by the Council on Medical Education and Hospitals of the American Medical Association, J A M A **161**:1668-1669 (Aug 25) 1956

The patients of physicians on the attending staff of community hospitals can be utilized in a program of continuing education if the other facilities and a teaching staff are provided, perhaps in part by cooperative arrangements between the regional hospitals and medical schools Such education if carefully planned and enthusiastically put into effect by the attending staff of the regional hospital would be more truly continuous education and thus more valuable than is likely to be the effect of sporadic study in formal courses However both kinds of programs—formal courses and regional hospital–medical school cooperative efforts—are necessary to meet the over-all needs of the profession

7 **METHODS OF EVALUATING the effectiveness of postgraduate programs should be developed**

Experiments directed toward ways of better accomplishing such evaluation are encouraged Evaluation should be concerned with the long term effectiveness of various programs as well as the more immediate improvement in the knowledge of those participating There are possibilities for instance through use of medical audits to evaluate results of courses and other educational programs in terms of better patient care Such audits in themselves may have educational implications

8 **Each PHYSICIAN'S REWARD for participation in postgraduate medical education always should be his improved ability to care for his patients and the stimulation of his own spirit of intellectual adventure**

Any certificate granted at the completion of a postgraduate program or series of programs should not be nor resemble a diploma attesting to special skill nor be reasonably susceptible of such interpretation Postgraduate medical education is not intended to provide an educational experience adequate for beginning the practice of a specialty or subspecialty That is the concern of graduate medical education, i e residency and fellowship training Therefore it would be inappropriate for any document attesting to postgraduate study to be subject to misinterpretation

SUMMARY

The basic principles of postgraduate medical education are the same as are those of undergraduate and graduate medical education In addition to students an effective program requires leadership careful planning suitable facilities and effective teachers who use dynamic methods of education that enlist the participation of the student For too long, the methods and facilities found lacking 50 years ago for effective undergraduate medical education have continued to be employed in many postgraduate courses and in some other activities labeled as educational for physicians

The Council on Medical Education and Hospitals expects that publication of this guide will be the first step in a long range program that will be of assistance in the improvement and increase of postgraduate educational activities After a suitable period following publication of this guide a continuing appraisal of postgraduate programs may be initiated

APPENDIX C

Straight Internships Versus Rotating Internships

The Advisory Committee on Internships in reporting the results of its study in 1952 favored the rotating internship over the straight internship This same attitude was expressed by the Ad Hoc Committee on Internships in reporting its study in 1954 The Council on Medical Education and Hospitals states in the Essentials of an Approved Internship (1955) It is the opinion of the Council that the best basic education is provided by a well-organized and conducted rotating internship The Council, however has continued to approve straight internships in Medicine Surgery, Pediatrics, and Pathology believing that this type of service may be justified in these fields for medical school graduates who have definitely determined to follow a specialized or academic career

At the June, 1956 Annual Session of the American Medical Association the Reference Committee on Medical Education and Hospitals considered two resolutions (Nos 11 and 38) favoring rotating internships, which were introduced into the House of Delegates The following is quoted from the Report of this Reference Committee as adopted by the House of Delegates

Your reference committee believes that there is a growing body of opinion within the profession in favor of a rotating internship It also recognizes the difficulties involved and the dangers to some established educational programs were action taken precipitously to disapprove straight internships which are about 10% of the total number now approved Your committee recommends the following substitute resolution for resolutions 11 and 38

Resolved (1) That the Council on Medical Education and Hospitals be requested to increase its efforts to encourage rotating internships rather than straight internships in all hospitals approved for the latter and (2) that a report of the results of this effort be submitted annually

Since June 1956 no new applications for straight internships have been approved by the Council pending clarification of policy in regard to this type of service Previously approved straight internships have maintained their approved status

In order that the Council might have adequate data and opinions on which to base its report to the House of Delegates, a letter was sent to the Administrator of each hospital offering approved straight internships requesting a statement regarding its attitude toward straight internships and whether or not they should be discontinued in favor of rotating internships It was suggested that this letter be shown to the Chief of each Service for which straight internships were approved and also to the Chairman of the Intern Committee in order that their individual views might be taken into consideration in expressing an opinion for the hospital

Ninety-two letters were sent out—to 63 hospitals affiliated with medical schools and to 29 nonaffiliated hospitals (An affiliated hospital is one which is listed as a major teaching hospital in the Internship and Residency Number of THE JOURNAL of the American Medical Association) Sixty-three replies were received from 46 affiliated hospitals (73%) offering 880 straight internships, and from 17 nonaffiliated hospitals (59%) offering 71 straight internships In the following table, the opinions expressed are summarized

	Affiliated Hospital	Nonaffiliated Hospital
Straight internships only should be allowed	7	1
Rotating internships only should be allowed	0	6
Both straight and rotating internships should be allowed	39	10
	46	17

Affiliated hospitals were unanimous in stating that straight internships *should not be discontinued* 85% of these replies indicated that there is a place for both straight and rotating services The majority (59%) of the opinions expressed by the nonaffiliated hospitals favored continuation of both types of internship, 35% favored discontinuation of the straight internships It should be noted in comparing opinions expressed that the great bulk (94%) of the straight internship positions represented by these figures lies with the affiliated hospitals

Opinions varied in almost every possible manner Individual opinions expressed by chiefs of services in the same hospital were at variance in some instances Some exact statements were received other expressions were practically unlimited as to space and subject matter Vehement statements were received from numerous hospitals and individuals, protesting the dictatorial attitude of the American Medical Association in attempting to regiment the type of internship

The principal arguments expressed for and against the straight internship and the rotating internship may be summarized as follows

STRAIGHT INTERNSHIP

Arguments for

1 A student is ready for specialized training at the internship level due to his having had a rotating service in his junior and senior years of undergraduate medical education

2 The straight internship is less likely to be a service internship than the rotating internship

3 The straight internship allows individualization to fit the needs of a particular student

4 The continuity of patient care is better, the supervision is better, greater responsibility can be delegated, and the intern becomes an integral part of a team

5 Reduces length of time necessary for graduate medical education

Arguments against

1 Straight internships should be limited to university hospitals where the attending staff is constantly available for instructional purposes

2 Interns on a straight service may be unhappy because they have selected the wrong specialty in which to train

ROTATING INTERNSHIP

Arguments for

1 Provides basic training in all branches of medicine, which is essential—the specialist first must be a good all around doctor

2 A graduate who is definitely planning to follow a specialized or academic career obtains maximum benefit from a preliminary rotating internship

3 The rotating internship is ideally suited to the needs of a physician entering general practice without additional training

4 It allows further time for choosing a specialty

5 It provides better rounded training and a firm foundation for future training and development

Arguments against

1 A rotating internship is an unnecessary repetition of fourth year medical school programs

2 Provides superficial experience because of rapid rotation—there is good breadth but little depth of experience

3 Provides only a superficial and often unsatisfactory contact with the subjects matter of each specialty

4 Provides inadequate educational experience either for the competent practice of medicine or as a groundwork for further specialization

5 There is a lack of thorough training in any area covered by the rotation service

6 Dilutes graduate training by giving superficial training in other specialties

7 Diversification may lead to a false sense of adequacy for practice in specialized fields for which he is not equipped

8 The degree of responsibility necessary for the rapid development of clinical abilities cannot be allowed

9 The rotating internship is too much trouble and is too unpredictable

10 With few exceptions, the service aspect predominates over the educational aspect in the rotating internship

11 In a university hospital the rotating internship results in certain areas of overlap and conflict between the activities and prerogatives of senior clerks and rotating interns

The following are direct quotations taken from replies received

FLEXIBILITY OF INTERNSHIP

1 The internship is an educational experience should be subject to continual change and evaluation for improvement

2 There is no fundamental conflict between the rotating internship and the straight internship They serve different purposes and as such they both deserve to be maintained

3 A greater emphasis should be placed on the educational value of an internship, and the question of whether it be of one particular type or another should be secondary

4 The value of an internship depends upon the quality, quantity and breadth of the experience To approve or disapprove of an internship because of the presence or absence of rotation seems illogical A good straight internship will always be better than a mediocre rotating service and vice versa

5 Our American system of medical education is respected because of the quality of our teachers, students, clinical facilities, and research opportunities, and not because of any particular schedule of teaching Is there any information which would indicate that graduates of straight internships have in the past made a smaller contribution to the community than graduates of rotating internships?

6 There is no one best way to handle a problem such as this, and it is not possible to take out a patent on any type of educational training program and exclude all others which have a proven worth

7 The field of medicine is too vast, too complex and too dynamic to justify the adoption of any one specific pattern of internship

8 The quality of an internship cannot be measured by its form, but only by its content and the quality of supervision and instruction

9 A rotating internship is superior to a straight internship in private or voluntary hospitals Where the hospital involved is a university hospital, or where the clinical service is under the direction of the medical school faculty, a straight internship may be equally desirable as training and in one respect is superior since it provides prolonged contact with teaching personnel

10 Perhaps the better teaching hospitals should band together to preserve the straight internship while encouraging good nonteaching hospitals to establish a rotating type designed for training of the practitioner

INTERFERENCE AND REGIMENTATION

1 The needs of the individual graduate and the resources and objectives of the individual hospitals will vary, hence the types and forms of the internship should vary We oppose any attempt by any group, governmental or private to regiment the form of the internship

2 To attempt to standardize or to restrict this important period of medical education is as improper as it is to regiment undergraduate education

3 We are unalterably opposed to the apparent intention of the American Medical Association to force the adoption of rotating internships throughout the country We believe the acceptance of such regimentation would seriously impair the capacity of our hospitals to provide their present superior level of internship training

4 Regimentation of the form of the internship can only discourage that quality of inventiveness which has been the greatest insurance of a high level of medical care for the American people

5 It is particularly desirable that the universities and the teaching hospitals affiliated with them be given wide latitude in experimenting with a variety of educational procedures It would be a mistake to interfere in an arbitrary manner and to force a degree of uniformity which is at odds with the traditions of this country

6 In a free society, the patterns of medical education in regard to internships will certainly be resolved by medical educators and their freedom of intelligent action should not be hampered by any special segment of the profession

7 The rise to excellence of American medicine is due in part to the high standards of the internship residency program If medical educators are to continue to improve this training and are to meet new demands and changing conditions, creativeness and the opportunity to experiment with various methods of education must be preserved and not be regimented out of existence

8 I view the proposal to prohibit the straight internship as a manifestation of the assumption of dictatorial powers by a democratic body, as the usurpation of the medical graduates right to exert some degree of choice in the type of postgraduate training he is to receive

9 Our hospital holds that the issue is not the virtues or faults of straight internships in comparison with rotating internships, but rather one of freedom in the conduct of educational programs A university affiliated hospital, one of whose primary functions is medical education, must resist the possible imposition of restrictions in the field of medical education by the action of any body within the medical profession Certainly our large teaching centers have a responsibility to experiment in educational techniques Any effort to regiment them or to curtail educational freedom must be vigorously opposed

10 While there is room for honest differences of opinion about the respective merits of straight versus rotating internships, there is certainly no defense for arbitrary and compulsory standardization in this sphere If standards of quality are

maintained it would be wise to permit a margin of freedom of choice and autonomy in approved institutions for the training of interns The regimentation, as the offering of only one type internship to medical school graduates, would act as a deterrent to the future progress and development of American medicine

MISCELLANEOUS QUOTATIONS

1 A straight medical internship is the best background for a man entering general practice

2 A two year internship with relatively long periods on each major service might well offer better preparation for general practice than is now readily available, as well as being an appropriate prelude to residency training

3 If obstetrics and gynecology cannot have its own straight internship and so appeal directly to fourth year medical students, then it would be better for us if everyone else had a rotating internship

4 The general practitioner of the future will be dealing largely with nonsurgical conditions and should be properly prepared in the disciplines of general medicine and perhaps should have experience in pediatrics and obstetrics

5 We believe that it would truly constitute a great step *forward if the sponsoring agencies of the Matching Plan* were to agree on a single reasonable stipend which would be the same for all hospitals

6 It seems likely that the Council and the House of Delegates might render an important service by emphasizing to the Department of Defense the importance to the military and civilian programs of changing their procedures so that a two year internship is practical

7 We would be approaching the future in a sounder fashion if the intern year were completely abolished

COMMENT

The preceding documentation of historical and statistical data together with a summarization of opinions obtained from responsible hospital administrators and medical educators has been presented as a report of progress for study by the House of Delegates Following further study of the internship, the Council will submit a definitive report and recommendations at a later date

RESOLUTIONS TO BE INTRODUCED AT NEW YORK MEETING

The Secretary of the Association has been informed that the following resolutions will be introduced in the House of Delegates at its session to be held in New York, June 3-7, 1957, by delegates from Nebraska, North Carolina, and Colorado respectively

No 1 Resolution on Establishment of Periodic Publication

WHEREAS The American Medical Association engages in numerous activities and provides numerous services in the health field, and

WHEREAS These activities and services are not known to many people in the health field including both members of the American Medical Association, as well as nonmedical people and

WHEREAS This lack of information is due primarily to lack of a mechanism of communication between the American Medical Association and those people in the field, therefore be it

Resolved That the American Medical Association establish a suitable regular periodic publication, preferably a Reader s Digest type of format, and be it further

Resolved, That this periodic publication be made available to all people in the health field for the primary purpose of informing them of the activities and services of the American Medical Association

No 2 Resolution on Proposed Changes in the Constitution and Bylaws

Resolved, That Article VIII of the Constitution shall be amended and on adoption by proper procedure shall read as follows

ARTICLE VIII—BOARD OF TRUSTEES

Section 1 Composition—The Board of Trustees shall consis of the general officers of the Association as defined in Articl VII, Section 1

Section 2 Term of Office—The term of each general office as a Trustee shall be for the same term of office he holds as an elected general officer as provided in the Constitution an Bylaws

Section 3 Duties—The Board of Trustees shall have charg of the property and financial affairs of the Association and shal perform such duties as are prescribed by law governing directors of corporations or as may be prescribed in the Bylaws

Resolved, That Chapter XVI, Section 1, of the Bylaws shall be amended and on adoption by proper procedure shall read as follows

CHAPTER XVI—BOARD OF TRUSTEES

Section 1 Composition—The Board of Trustees shall consist of the general officers of the Association elected as provided for in Article VII of the Constitution The term of the general officers as Trustees shall be for the same term each holds as a general officer

No 3 Resolution on Free Choice of Physician

WHEREAS, The time-honored right of the American citizen freely to choose his physician from among all those available and legally qualified has contributed immeasurably to the advancement of American standards of medical care to their present world preeminence, and

WHEREAS, Deterioration in the quality of medical care rendered has developed in systems of medical care which deny patients this traditional American right, and

WHEREAS, The definition of the free choice of physician in the Principles of Medical Ethics of the American Medical Association recognizes the validity of interest of a third party interjected between the patient and his choice of physician only when that third party assumes legal and financial responsibility for occupational disease or injury, and

WHEREAS, This House of Delegates reiterated its adherence to this free choice principle as a fundamental right of American citizens which contributes to the betterment of medical care by unanimously adopting Resolution No 24 at the June, 1956, Chicago Session, thereby directing the Councils on Medical Service and Industrial Health to revise their published 'Guiding Principles for Evaluating Management and Union Health Centers to conform to the free choice principle now therefore be it

Resolved, That this House of Delegates again reiterates the adherence of the American Medical Association to the principle of the free choice of physician as currently defined in the Principles of Medical Ethics as being essential to the welfare of the patient, and be it further

Resolved, That the Judicial Council is requested to caution all members of the American Medical Association that voluntary participation in systems of medical care which deny patients their right of free choice of physician as so defined, other than as may be required by the mandates of law, constitutes a violation of the Principles of Medical Ethics

CONTINUOUS HEALTH SUPERVISION OF CHILDREN

The National Congress of Parents and Teachers has promoted, since 1925, the medical examination of children on school entrance in what has been called the 'Summer Round-up' This program has had the support of the American Medical Association and many state medical societies However, for several years physicians have felt such a program was inadequate and undesirable in many ways Therefore, in January, 1956, the National Congress asked representatives of 20 organizations interested in child health to advise them on how to extend this single examination into a more effective program of child health supervision This health advisory committee made a proposal which was accepted by the board of managers of the National Congress of Parents and Teachers in May, 1956 Essentially, this is

> I That the National Congress of Parents and Teachers adopt a policy supporting and encouraging a program of continuous health supervision of children from birth through their school experience, rather than only a program of single appraisal on school entrance
>
> II That the National Congress of Parents and Teachers recommend to its local units a promotional and educational program that will tend to bring children and their parents into effective contact with the health resources of the community Wherever possible, these should be the physician and dentist who normally serve the child or family, whether they be working in private practice or in a community health service

The American Medical Association was represented on the health advisory committee of the National Congress of Parents and Teachers by the Chairman of the Committee on Maternal and Child Care of the Council on Medical Service and the Director of the Bureau of Health Education It is reasonable, therefore, that these units of the American Medical Association should cooperate with the National Congress in promoting the concepts envisioned by this revised program

One facet of this cooperation is the action taken by the Council on Medical Service On April 13, 1957, the Council approved the following resolution made by its Committee on Maternal and Child Care

> The Maternal and Child Care Committee of the Council on Medical Service, American Medical Association reaffirms its approval of the principle of continuous health supervision of children from birth through their school experience rather than only a program of a single appraisal on school entrance It also recommends that where possible, this should be done by the physician and *dentist who normally serve that child and family* preferably his personal physician and dentist The Committee welcomes the support of the National Congress of Parents and Teachers

It is the hope of the Council on Medical Service that physicians will give every possible assistance to the local parent-teacher associations to insure the medical soundness of their proposed program

The Bureau of Health Education of the American Medical Association submitted this proposed program to the Joint Committee on Health Problems in Education, a long-established joint committee of the National Education Association and the American Medical Association The Joint Committee has made the following statement

> The Board of Managers of the National Congress of Parents and Teachers adopted a resolution on May 24, 1956 urging local Parent-Teachers Associations to inaugurate a promotional and educational program that will tend to bring children and their parents into effective contact with the health resources of the community (medical, dental and public health) The Board of the Congress adopted a policy supporting and encouraging a program of continuous health supervision of children from birth through their school experience by physicians and dentists normally serving the family rather than only a program of single appraisal on school entrance
>
> The Joint Committee on Health Problems in Education at its annual meeting on March 11, 1957, reiterates its long standing belief in the concepts and philosophy expressed in this proposal and commends the extension of such programs of continuous supervision to parents to school to health and other community groups

Under the leadership of Dr Henry F Helmholz, health chairman of the National Congress of Parents and *Teachers, state and local chairmen of parent-*teacher association groups are being urged to make contact with their local medical societies, local or state chapters of the American Academy of Pediatrics and American Academy of General Practice, and other groups concerned with child health at the state and local level It is hoped that there will be complete cooperation among the professions and organizations interested in the health of children from birth through the school years, so that a true child-centered program can be developed This hope is reiterated by Dr Helmholz in a Guest Editorial in this issue of THE JOURNAL (page 52)

The Parent-Teacher Association has no interest in dictating medical care policies but will concentrate its attention on parent education and community organization concerning periodic health appraisal and continuous health supervision

As stated in the various resolutions, it is preferable that health supervision be the responsibility, wherever possible, of the physician and dentist who normally serve that particular child Here is an unusual opportunity for physicians to work with community organizations that have a mutual interest in the health of children and the extension of the single-examination Summer Round-up into a continuing child health supervision activity

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

POSTGRADUATE COURSES

A 5 day 40-hour postgraduate course on **medical otolaryngology** will be offered May 27-31, 1957, to full-time specialists This course on headaches, immunology, and allergy as related to otolaryngology will consist of laboratory work, lectures, panel discussion, open question periods, and audiovisual aids It will be held in a hotel The fee is $150 For further information, write to the Hansel Foundation, 634 N Grand Ave, St Louis 3

Postgraduate Course on Poliomyelitis

It has been reported to the Council that the dates of the postgraduate course in poliomyelitis treatment offered by the Children's Medical Center, Boston, have been changed The 40-hour 5-day course will be offered twice this summer June 10-14 and Aug 5-9, inclusive Methods of education include patient demonstrations, live clinics, ward rounds, seminars, lectures, panel discussions, open question periods, and visual aids Enrollment is open to physicians in general practice and in part-time specialty practice at a fee of $50 For further information, write to Assistant Director of Clinics, Children's Hospital, 300 Longwood Ave, Boston 15

MEDICAL NEWS

CALIFORNIA

Infectious Encephalitis—The U S Public Health Service states in its morbidity and mortality weekly report for March 22 that the California State Department of Public Health has supplied a summary of acute encephalitis cases reported in 1956 From a total of 560 cases, 14 were laboratory confirmed cases of western equine and 7 were St Louis types of infection About 45% of the total were reported as mumps encephalitis Of 1,047 pools of mosquitoes tested, 143 yielded WEE virus and 2 the St Louis virus Laboratory confirmation of cases in horses was obtained in only six animals During 1956, 124 squirrel brains were submitted for rabies examination but none was positive for this infection WEE virus was isolated from four of these animals

Appoint Acting Dean—Dr Robert H Alway, executive head, department of pediatrics, Stanford University School of Medicine, Stanford University–San Francisco, was named acting dean of that institution March 8 He replaces Windsor C Cutting, who resigned as dean in January but continued in the post until a successor could be found A graduate of the University of Minnesota Medical School, Minneapolis, Dr Alway joined the Stanford medical faculty in 1949 after teaching six years at the University of Utah School of Medicine, Salt Lake City He became head of pediatrics at the University of Colorado School of Medicine, Denver, in 1953 but returned in 1955 to assume a similar post at Stanford Former dean Cutting will continue as professor of pharmacology, resuming the teaching and research which was curtailed by his appointment as head of the school in 1953

GEORGIA

Seminar on Kidney Diseases—The Atlanta Pathology Seminar Group announces that Dr Arthur C Allen, associate pathologist, Memorial Center for Cancer and Allied Diseases, New York City, will moderate a seminar on kidney diseases May 10 in the auditorium of the Fulton County Medical Society, Atlanta The seminar will be followed by a lecture, 'Clinicopathologic Meaning of the Nephrotic Syndrome"

Personal—Dr Harry D Bruner, chairman, department of physiology, Emory University School of Medicine, Atlanta, Ga, since 1952, has been named chief of the medical branch, Division of Biology and Medicine, Atomic Energy Commission, Washington, D C For three years prior to joining the Emory staff, Dr Bruner had served as a chief scientist with the Oak Ridge Institute of Nuclear Studies medical division —Dr E James McCranie, Augusta, has been named a professor in the department of psychiatry, of the Medical College of Georgia —Dr George Williams Smith, Augusta, has been appointed associate professor of surgery and chief of neurosurgery at the Medical College of Georgia

ILLINOIS

Chicago

Lecture on History of Surgery—Chauncey Leake, Ph D, Ohio State University School of Medicine, Columbus, will present the 10th and final lecture in the present series on the history of surgery on May 14, 8 p m, at the International Surgeons Hall of Fame, 1524 Lake Shore Drive Dr Leake's subject will be The Rise of Modern Surgery' The lecture, sponsored by the International College of Surgeons, is open to the medical profession and the public

Personal—The James Alexander Miller Fellowship for the year beginning July 1 has been announced by the New York Tuberculosis and Health Association The grant of $7,000, made annually to support fundamental medical research in tuberculosis, will go to Dr John E Kasik, a senior assistant resident physician in the department of medicine at the University of Chicago Clinics The antituberculosis drug, cycloserine, will be the subject of Dr Kasik's research

Howard Sloan Grant—The annual Dr Howard Sloan Physiology Grant of $500, in commemoration of the birthday of Dr Sloan, has been made to the Chicago Medical School An alumnus of the school, Dr Sloan was also a fellow in the department of physiology at the time of his death in 1952 He had achieved recognition for his research on the artificial kidney The grants have been used for the purchase of special equipment for cancer research in the physiology laboratories and to support important studies

First May Cave Willett Fellow—Dr Kurt Aterman, senior lecturer, department of anatomy, Medical School, Birmingham, England, has been appointed the first May Cave Willett research postdoctoral fellow at Chicago Lying-in Hospital of the University of Chicago The appointment, supported through a grant of $100,000 by Mr Howard Willett Sr, president, Willett Motor Coach Co, Chicago, in honor of his wife, is one of the first made to initiate Chicago Lying-in Hospital's new type research program in the physiology of reproduction

Northwest Suburban Tuberculosis Clinic—A new tuberculosis outpatient and treatment clinic operated by the Suburban Cook County Tuberculosis Sanitar-

---

Physicians are invited to send to this department items of news of general interest for example, those relating to society activities, new hospitals, education, and public health Programs should be received at least three weeks before the date of meeting ium District has opened in the new Northwest Suburban Clinic Building, 1430 North State Road, Arlington Heights The clinic will serve residents of the northwest area of Cook County and will meet every Tuesday from 10 a m to 12 noon It will continue in the Arlington Heights building until such time as a hospital is built in the northwest area when the District will provide outpatient care and x-rays through the hospital facility

LOUISIANA

Personal —The gold medal of the Buffalo (New York) Surgical Society was awarded in February to Dr Alton Ochsner, New Orleans, who at the same time made the 10th Roswell Park Lecture His subject was "Bronchogenic Cancer—Factors Which Influence Long-Term Survival"

Laboratory for Metabolic Research —The Urban Maes Laboratory for endocrine and metabolic research was recently established in New Orleans under the auspices of the Urban Maes Research Foundation and the joint sponsorship of the Louisiana State University and Tulane University schools of medicine and Touro Infirmary, New Orleans Temporary facilities will be established at the Louisiana State University School of Medicine, New Orleans, until a permanent laboratory is constructed at Touro Infirmary Dr Floyd R Skelton is director of the laboratory

MARYLAND

Dr Clark to Receive Passano Award —The board of directors of the Passano Foundation recently announced that William Mansfield Clark, Ph D , professor emeritus, department of biological chemistry, Johns Hopkins University School of Medicine, Baltimore, has been selected as the recipient of the $5,000 Passano Foundation Award for 1957 On June 5 a reception and dinner will be held at the Waldorf-Astoria Hotel to honor Dr Clark Dr David B Allman, incoming president of the American Medical Association, will be one of the speakers The award is made to Dr Clark in recognition of his distinguished career as investigator and teacher, and for his demonstration over the years of the importance of physical methods notably in the control of pH and of oxidation-reduction to the study of life processes

MICHIGAN

Personal —The first annual Chamberlain Lecture on cardiovascular roentgenology at the Temple University Medical Center, Philadelphia, was given recently by Dr Melvin M Figley, assistant professor of radiology, University of Michigan Medical School, Ann Arbor

Health Records —According to the 1956 vital statistics released by the Michigan Department of Health, six new health records were set by the state last year All-time highs were set in birth rate (27 4), total births (205,650) All-time lows were set in total death rate (8 5) and in death rate among infants under one year of age (24 6)

NEBRASKA

State Association Meets in Omaha —The 89th annual session of the Nebraska State Medical Association will be held May 13-16 at the Hotel Paxton, Omaha Dr Dwight H Murray, president of the American Medical Association, will speak on 'Idealism Is Not Old-Fashioned,' at the annual banquet May 15 Dr Gonzalo Obregon, assistant professor in otolaryngology, State University of Iowa College of Medicine, Iowa City, will speak on "Office Laryngoscopy,' and will present a movie on the technique of indirect laryngoscopy Topics by great speakers include

Cardiac Resuscitation, Robert M Hosler Cleveland
The Environment of the Premature Infant, William A Silverman, New York City
Hemorrhage in the Third and Fourth State of Labor, Frederick J Hofmeister, Milwaukee Wis
Modern Management of Congestive Heart Failure O Earle Gray, Chicago, Ill
Social Security Coverage for Physicians and the Keogh Jenkins *Bills, Ernest B Howard assistant secretary, the American Medical Association, Chicago*

Entertainment activities include a golf tournament, trap shoot, sportsman s dinner, bowling, and special ladies' program Information may be obtained from the Nebraska State Medical Association, 1315 Sharp Building, Lincoln 8

NEW YORK

Personal —Dr Hilary Koprowski, formerly assistant director of viral and rickettsial research, Lederle Laboratories, American Cyanamid Company, Pearl River, N Y , has been appointed director of the Wistar Institute, Philadelphia

Appoint Director of Medical Education —Dr Bernard Levinson, of Salt Lake City, has been appointed director of medical education, effective July 1, at the State University of New York College of Medicine, Syracuse Dr Levinson will also become instructor in medicine at the college succeeding Dr Edward J Heitzman, who will enter private practice and will remain on the faculty as clinical instructor

Research Training Grant —A $6,900 grant by the U S Public Health Service was made to Albany Medical College to establish a research training program in its physiology department Administered by Dr Matthew N Levy, associate professor of physiology, it supplements an $11,774 grant he received from the same agency last year for a study of peripheral resistance to blood flow

Muscular Dystrophy Grant —Dr Willet R Bowen, department of pediatrics, Wilfred W Westerfeld, Ph D , chairman, department of biochemistry, and Dr Charles W Linart, orthopedic surgeon, State University of New York College of Medicine, Syracuse, are the recipients of a $9,000 grant from the Muscular Dystrophy Associations of America for research in progressive muscular dystrophy

Research on the Psychiatric Interview —A research grant of $31,700 has been awarded to Hillside Hospital, Glen Oaks, Queens, N Y , by the Foundations

Fund for research in psychiatry The grant was given to Dr Joseph Jaffe, of the hospital's department of experimental psychiatry, for research in the nature of the psychiatric interview The research was begun in 1955 The grant will pay for work conducted in 1957 and 1958

Psychiatric Research Project at Sing Sing—Dr Samuel L Dunaif, instructor in psychiatry, Columbia University College of Physicians and Surgeons, New York City, has been appointed to carry out a joint psychiatric research project at Sing Sing prison for the state departments of mental hygiene and correction Serving on a part-time basis, he will set up a pilot study to delineate, wherever possible, the areas of research concerning the various types of offenses Some areas he will explore include (1) the problem of recidivism, (2) whether the newer drug therapies will be of any value in control of recidivism, and (3) whether the symptom-producing drugs have a different reaction in various types of offenders He also will follow cases in which shock therapy has already been given Dr Dunaif served as a resident research psychiatrist for two years and as a consultant research psychiatrist for one year on a previous study of convicted sex offenders at Sing Sing

New York City

Dr Hass Awarded Prize—Dr Julius Hass has been awarded the Umberto I" prize, under the auspices of the Orthopedic Instituto Rizzoli, Bologna, Italy, for his monograph on Congenital Dislocation of the Hip" The prize is an international award consisting of a gold medal and a diploma and is given every five years for the best work in the field of orthopedic surgery

Bernard Sutro Oppenheimer Lecture—Dr Dickinson W Richards, Lambert Professor of Medicine, Columbia University College of Physicians and Surgeons, and director of the First Medical (Columbia) Division Bellevue General Hospital, will deliver the first Dr Bernard Sutro Oppenheimer Lecture May 21 at 8 30 p m in Hosack Hall at the New York Academy of Medicine 2 E 103 St The title of Dr Richards lecture will be 'Some Problems in the Physiology of Dyspnea"

Personal—Dr Thomas M Rivers, New York City, formerly vice-president of the Rockefeller Institute for Medical Research, has been appointed medical director of the National Foundation for Infantile Paralysis He succeeds Dr Hart E Van Riper, New York City, who resigned to become medical director of Geigy Pharmaceuticals ——Dr Joseph M Pisani has resigned as assistant dean of the New York University College of Medicine in Brooklyn to become full-time medical director of Bankers Trust Company, New York City, effective April 1

Hospital Centennial—The 100th anniversary committee of Lenox Hill Hospital will plan and direct a four-day celebration May 10-13 to mark the hospital's century of service The celebration will highlight the advances made in medical science since the hospital was founded Open to the public will be a program of panel discussions by leading medical scientists of Lenox Hill's professional staff on current trends in medical progress and accomplishments Scientific exhibits and guided tours of the hospital will dramatize the extent of Lenox Hill's service to New York for the past 100 years

New Hospital in Queens—The 970 bed Elmhurst General Hospital, erected at a cost of 25 2 million dollars on an 8 5 acre triangular plot bounded by Broadway, 78th Street, 41st and Baxter avenues, began receiving patients March 18 The hospital consists of two eleven story buildings and a five-story building, all interconnected A photofluorography room for preadmission chest examination, chapels for the three major religious faiths available for the use of patients, a library, an auditorium, and extensive rehabilitation facilities are among the features A premature center has 18 bassinets The operating room suite has a tissue laboratory and its own x-ray facilities A control room for televised closed-circuit medical education programs and a psychiatric service of 154 beds are provided

NORTH CAROLINA

Personal—Dr Warner Lee Wells, assistant professor of surgery, University of North Carolina School of Medicine, was recently named the winner of the 1957 O Max Gardner Award The award is given each year "to that member of the faculty of the Consolidated University of North Carolina, who, during the current scholastic year, has made the greatest contribution to the welfare of the human race"

Psychiatric Nursing—A $31,874 grant for research in psychiatric nursing has been made to Duke University, Durham, by the National Institute of Mental Health The two-year grant will permit continuation and expansion of a project headed by Dr Robert H Dovenmuehle, chief of inpatient service in the psychiatric department The project is centered around defining the nursing activities which will contribute to effective psychiatric care Also, the Duke researchers will study the characteristics of the nurse who can best do this type of work

OHIO

Personal—Margaret Mead, Ph D , New York City, anthropologist, has been added to the faculty at the University of Cincinnati College of Medicine as part-time visiting professor of anthropology Dr Mead will work with Dr Maurice Levine, professor of psychiatry and director of the university department

Tuberculosis Detention Facility—A 19 bed facility for the detention of tuberculosis patients who are declared a 'public health menace' in probate courts will open in the spring or early summer at Ohio Tuberculosis Hospital, Ohio State University, Columbus The faculty will provide security and treatment for some of the flagrant offenders against public health

Paul Lewis Award—G Robert Greenberg, Ph D , associate professor of biochemistry, Western Reserve University School of Medicine, Cleveland, received the $1,000 Paul-Lewis Laboratories Award in Enzyme Chemistry at Miami, Fla , April 8, during the 131st national meeting of the American Chemical Society His award address was on Biosynthesis of Purines The award was established in 1946 by the Paul-Lewis Laboratories, Inc , Milwaukee, Wis , to stimulate research in the field of enzymes

OKLAHOMA

Establish Lhevine Memorial—Friends of the late Dr Morris B Lhevine, Tulsa radiologist who died last year, have created an annual scholarship in his memory to Technion, the Israel Institute of Technology, it was announced in Haifa recently Dr Lhevine in 1951 visited Israel and consulted with national leaders on the development of technical education

Expand Program at Children's Center—Children's Medical Center, of Tulsa, was named last month as headquarters for a regional training program for personnel to work with mentally retarded children Financed by a grant of $55,000 from congressional appropriations, the program will utilize 11 instructors to train personnel in advanced techniques for handling and developing the mentally retarded child It will be set up on a three-year basis and will utilize the physical facilities of the center, the Tulsa Child Guidance Clinic, and Sunnyside School Dr Paul C Benton, medical director and administrator of the center, will serve as director and psychiatric consultant for the new program

PENNSYLVANIA

Training Program in Cancer—The University of Pittsburgh Graduate School of Public Health announces a new program of advanced study and field training for students interested in cancer and other chronic diseases This is the first training program of its kind to be supported by the National Cancer Institute and will require an annual budget of about $100,000 for five years The grant from the institute will be matched in equal amounts by funds from the school Inquiries concerning admission to the program and fellowships should be addressed to the Dean, Graduate School of Public Health, University of Pittsburgh, Pittsburgh 13

Philadelphia

Temple Alumni Reunion—The Class of 1937, Temple University School of Medicine, Philadelphia, will have its 20th year reunion at the Warwick Hotel June 8 Dean William N Parkinson and 12 former professors will participate in the activities and program For information write Dr Harry Shubin, Chairman, 6601 N 21st St , Philadelphia 38

Exhibit Civil Defense Hospital—The Federal Civil Defense Administration's 200-bed emergency hospital unit was exhibited in Philadelphia April 1 by the Philadelphia Civil Defense Council Dr Isidor S Ravdin officially opened the hospital unit A highly mobile, self-sufficient disaster unit, the hospital has 288 different types of equipment, including a 1500-gallon nylon rubber collapsible tank to provide its own water supply, five folding operating tables, and a portable x-ray unit, complete with its own generator and transformer, capable of turning out 60-second x-rays This 200-bed unit is intended to provide early treatment of seriously sick and injured casualties as close as possible to the stricken area in times of disaster or attack The hospital is also expected to be an invaluable peacetime training aid for all civil defense medical, nursing, and applied services

SOUTH CAROLINA

Eye Bank Group Organized—The South Carolina Eye Bank, Inc , a clearing house for eye donations, held an organizational meeting recently in Columbia Organization of the bank was made possible by an act of the South Carolina General Assembly last year Clearing house for the organization will be in Columbia The bank and laboratory will be maintained at the Medical College of South Carolina Dr Clay W Evatt of Charleston was named medical advisor to the organization The organization is to establish and operate an eye bank and corneal eye clinic to be organized and operated exclusively for obtaining eyes and corneal transplants

WEST VIRGINIA

Appoint Chief of Gerontological Service—Dr Thomas H McGavack, professor of clinical medicine, resigned from New York Medical College, Flower and Fifth Avenue Hospitals, New York City, in order to accept appointment as chief, gerontological service, Veteran s Administration Center, Martinsburg He has been given professorial rank at George Washington University School of Medicine, Washington, D C , where he will conduct conferences on endocrine, metabolic, and gerontological subjects

Personal—Dr Hiram W Davis, Huntington, who has been superintendent of Huntington State Hospital for six years, has resigned to become state commissioner of mental hygiene and hospitals in the state of Virginia, succeeding Dr Joseph E Barrett, who resigned to return to the post of superintendent of Eastern State Hospital at Williamsburg Dr Davis is chairman of the section on neurology, neurosurgery, and psychiatry, West Virginia State Medical Association, and is a member of the committee on mental hygiene

WISCONSIN

Conference on Work and the Heart—A medical conference on Work and the Heart" will be conducted at Marquette University, Milwaukee, May 15-18 The participants will include some 60 of medical authorities and specialists from four foreign countries Sponsored by the Marquette University School of Medicine and the Wisconsin Heart Association, the conference will be divided into five concurrent panels on basic physiology, clinical physiology, pathology, work classification, and workmen s compensation Foreign participants include Drs H H Weber, of Heidelberg, Germany, Matti J Karonen, of Helsinki, Finland, A Morgan Jones, of Cheshire, England, and Gunnar Birock, of Malmo, Sweden

University News—Dr Herwig Hamperl, director of the Institute of Pathology, University of Bonn, Germany has been designated Carl Schurz Professor of Pathology, University of Wisconsin Medical School, Madison, for the second semester of the academic year 1957 —The University of Wisconsin Medical School will dedicate the Bardeen Medical Laboratories May 17 This unit, named for Dr Charles Bardeen first dean of the Wisconsin Medical School will afford space for the department of anatomy and physiological chemistry The entire top floor will contain animal quarters The dedication will coincide with Alumni Day and speakers will include Drs Eugene L Opie emeritus professor of pathology, Cornell University Medical College, New York City, George Corner, professor emeritus of embryology, Johns Hopkins University School of Medicine, Baltimore, and Willard C Rappleye, dean, Columbia University College of Physicians and Surgeons, New York City

GENERAL

Health Meeting in Long Beach—The 24th annual meeting of the Western Branch, American Public Health Association, will be held in Long Beach, Calif, May 29-June 1 at the Lafayette Hotel Special sessions on epidemiology, public health education, sanitation, laboratory, nutrition, and industrial hygiene will be held For information write Dr Irving D Litwack, Department of Public Health, City of Long Beach, Calif

Education and Public Health Grant—For the support of its field services in medical education and public health in 1957, The Rockefeller Foundation has appropriated $371,625, an increase of more than $50,000 over the amount appropriated for 1956 For the promotion of medical education and public health throughout the world, the foundation maintains regional offices in Brazil, Chile, and India, and the opening of a new Middle Eastern office is planned for 1957 if political conditions permit

Meeting of Medical Technologists—The silver anniversary convention of the American Society of Medical Technologists will be held at the Palmer House in Chicago, June 23-29, at which study groups and workshops will be presented The study groups will consist mainly of lectures and demonstrations emphasizing individual participation in chemical protein industry, cytology and histology, and tissue culture The workshops will be held at various hospitals and schools in the Chicago area on hematology, mycology, and photography (gross photography and photomicrography) The executive office of the American Society of Medical Technologists is at 25 Hermann Professional Building, Houston 25, Texas

Muscular Dystrophy Clinic—A muscular dystrophy clinic has been opened at the University of Texas School of Medicine, Galveston, as part of a $250,000 research project being sponsored jointly by the school and National Muscular Dystrophy Research Foundation, Inc, Liberty, Texas The Medical Branch will take two muscular dystrophy patients a week, so that intensive studies may be carried out Later more patients will be admitted Besides the clinical work, the project includes experiments with a new strain of white mice which has a disease similar, and perhaps identical, to muscular dystrophy Eleven systematic studies are being proposed for other methods of investigation and research

Blood Transfusion Survey—Dr Frank E Wilson, executive vice-president of Joint Blood Council, Washington, D C, has announced the launching of a nation-wide survey of blood transfusion services The two-year study, made possible by a U S Public Health Service grant of $50,000 will collect, analyze, and disseminate information Objectives include preparation of guidelines and standards for accreditation of blood banks, development of a glossary of terms and solution of numerous nomenclature problems, inventory of research in blood and blood derivatives, and the assembling and analysis of needed data appertaining to these objectives

Woods Schools Spring Conference—Vocational training and rehabilitation of the mentally and physically handicapped will be the concern of national leaders in the field at the Spring Conference of the Woods Schools, Langhorne, Pa, to be held May 10-11 in the School of Law, Northwestern University, Chicago Keynote speaker will be Samuel A Kirk, Ph D, director of the Institute for Research on Exceptional Children, University of Illinois, Urbana Dr Frederic A Gibbs, professor of neurology at the College of Medicine, University of Illinois, Chicago, will speak on 'The Need for Medical Evaluation in Vocational Guidance and Training"

Announce Fellowship in Proctology—The International Academy of Proctology announces the establishment of a teaching and research fellowship in proctology under the direction of Dr Marcus D Kogel, dean of the Albert Einstein College of Medicine, New York City The academy has voted a $1,000 annual grant for each of three years to assist in the development of research and educational projects in proctology at the university One of the projects developed under this grant has been a tissue slide 'library for teaching purposes, under the direction of Dr Alfred A Angrist, clinical professor of pathology, New York Medical College, Flower and Fifth Avenue Hospitals, New York City For information write International Academy of Proctology, 147-41 Sanford Ave, Flushing, N Y

Radium Society Meets in Quebec —The 39th annual meeting of the American Radium Society will be held at the Chateau Frontenac, Quebec, Canada, May 29-June 1 The Gordon E Richards Memorial Lecture, 'Newer Knowledge of the Structure of Normal and Malignant Cells Obtained by Electron Microscopy,' will be given by Dr Arthur W Ham Toronto, Ontario The Janeway Lecture, 'Contributions of Biology to Radiation,' will be given by Dr Simeon T Cantril, Seattle A round-table conference, 'Treatment of Cancer of the Lung,' will be moderated by Douglas Quick M B, New York City A symposium on 'Rotation Therapy' will include a round table discussion moderated by Dr Robert Robbins, Philadelphia The annual banquet will be held May 31, 7 30 p m For information write Theodore R Miller, 139 E 36th St, New York 16

New Journal on Mental Deficiency —The first number of the *Journal of Mental Deficiency*, sponsored by the National Society for Mentally Handicapped Children, Ltd, will appear this spring The journal is administered by an advisory committee under the chairmanship of Prof Lionel S Penrose, with Dr Barry W Richards as editor Articles on all aspects of mental deficiency will be included, but there will be a medical bias and a high proportion of available space will be allotted to papers reporting the results of original research The journal will appear twice a year in the first instance and will become quarterly should this be justified by the quantity and quality of subject matter submitted The journal will cost $1 50 Inquiries and contributions should be sent to Dr B W Richards, St Lawrence's Hospital, Caterham Surrey, England

Cardiologists Meet in Washington —The sixth annual meeting of the American College of Cardiology will be held at the Hotel Willard, Washington, D C, May 15-18 Two seminars, 'Electrocardiography and Vectorcardiography," and "Congenital Heart Disease,' and symposiums on pericarditis with effusion and constrictive pericarditis, diagnostic methods (two parts), and open heart surgery are scheduled The Franz Groedel Lecture, Humanities in Medicine,' will be given by Dr Henry Borsook, professor of biochemistry, California Institute of Technology, Pasadena, Calif The annual convention guest lecture will feature Dr Frank B Berry, assistant secretary of defense for health and medicine, and Dr Ignacio Chavez, director, National Institute of Cardiology, Mexico City, Mex, who will speak on "Evolution of Diagnosis in Cardiology in the Last 30 Years' Panel discussions will follow presentation of formal papers at each session "Fireside Conferences' are scheduled for May 16, 10 p m Tours of Washington and trips to Alexandria and Mt Vernon are planned The annual banquet will be held May 17, 7 45 p m ($10 a person) A specially arranged closed T V broadcast on cardiology originating from the National Heart Institute is scheduled for May 15

Announce Allergy Fellowships —The scientific and educational council of the American Foundation for Allergic Diseases has announced a research and training program to encourage medical education in allergic diseases Four classes of fellowships are offered

1 Predoctoral Fellowships—Two predoctoral fellowships of $2500 have been awarded for 1956 1957 to Louis G Hoffman and Jack Litwin both working in microbiology at Johns Hopkins University and the University of Chicago respectively
2 Part-Time Fellowships—Forest E Brown, Harvard University Boston working in immunology has been awarded $1500
3 Postdoctoral Fellowships—Three such fellowships in research and clinical allergy have been established at Johns Hopkins University, Baltimore Pennsylvania University Philadelphia and Washington University St Louis They carry stipends of $4500 for the first year $4750 for the second year and laboratory and travel expense of $750 for the two year period Applications for these are now available from the research directors at the three medical schools The deadline is May 10 Funds were made available by a grant from Mr John D Rockefeller Jr
4 Summer or Quarterly Predoctoral Fellowships—Twenty quarterly or summer fellowships are available for students who have completed two years of medical school training They are for a minimum of eight weeks and the stipend is $500 Deans of all approved medical schools have been invited to nominate candidates by April 30 A grant from the Gustavus and Louise Pfeiffer Foundation made these fellowships available

Society News —Officers of the **Central Society for Clinical Research** include Dr Kenneth Kohlstaedt, Indianapolis, president, Dr Thornton Scott, Lexington, Ky, vice-president, and Dr William S Jordan Jr, secretary-treasurer (Western Reserve University, 2109 Adelbert Rd, Cleveland 6) —The recently elected officers of the **Association for Research in Nervous and Mental Disease** include president, Dr Francis J Braceland, Hartford, Conn, first vice-president, Dr Paul Hoch, second vice-president, Dr Carl Pfeiffer, secretary-treasurer, Dr Rollo J Masselink, New York City, and assistant secretary, Dr Lawrence C Kolb, New York City The 37th annual meeting will be held at the Hotel Roosevelt in New York City, Dec 13-14 —The **National Multiple Sclerosis Society** has moved from 270 Park Ave, New York 17, to new quarters at 257 Fourth Ave (phone ORegon 4-4100) The society, which was established in October, 1946, has nearly 100 chapters and branches from coast to coast It is supporting major scientific research into the cause and cure of multiple sclerosis In 1956 the society allocated $270,805 for research, and more than $450,000 is already earmarked for research support this year —The **American Heart Association** announces that the deadline for submission of abstracts of papers for presentation at its scientific sessions (Oct 25-28, Hotel Sherman, Chicago) is June 15 Papers intended for presentation must be based on original investigations in, or related to, the cardiovascular field Abstracts must be submitted in triplicate on forms obtainable from the Medical Director of the Association, 44 E 23rd St, New York 10, N Y

Abstracts should not exceed 300 words and should contain in summary form the results obtained and the conclusions reached —**The American Public Health Association** recently elected the following officers president, John W Knutson, D D S, Washington, D C president-elect, Roy J Morton, C E, Oak Ridge, Tenn, chairman of the executive board, Lawrence J Peterson, M S P H, Boise, Idaho, and treasurer, Charles Glen King, Ph D, New York City Dr Reginald M Atwater, New York City, is executive secretary The next annual meeting will be held in the Cleveland Public Auditorium, Nov 11-15 —At the annual meeting of the **American Academy of General Practice**, the congress of delegates adopted an amendment which now requires a one-year rotating internship as an absolute minimum requirement for membership The academy also named Dr Holland T Jackson, Fort Worth, Texas, president-elect Dr Malcom E Phelps, El Reno, Okla, was inducted as president —The officers of the **American Academy for Cerebral Palsy** for 1957 are Dr Nicholson J Eastman Johns Hopkins Hospital, Baltimore, president, Dr William T Green, Harvard Medical School, Boston president-elect Dr Raymond R Rembolt, State University of Iowa College of Medicine, Iowa City Iowa secretary-treasurer

CANADA

Society News —At the 20th annual meeting of the Canadian Association of Radiologists held in Montreal in January, the following officers were elected for the year 1957 Drs Jean L Bouchard, Montreal, president, Andrew R McGee, Toronto, vice-president, Guillaume Gill Montreal, honorary secretary-treasurer, Robert G Fraser Montreal, associate honorary secretary-treasurer

FOREIGN

Congress of Group Psychotherapy —The Second International Congress of Group Psychotherapy will be in Zurich, Switzerland, Aug 29-31, preceding the Second International Congress of Psychiatry The president of the congress is Dr Jacob L Moreno, New York City The program chairman, Dr Serge Lebovici, (Paris) France For information write Wellman J Warner, Ph D, 812 Stuart Ave, Mamaroneck N Y

Pacific Science Congress —The ninth Pacific Science Congress will be held in Bangkok, Thailand, Nov 18-Dec 9, under the auspices of the government of Thailand and the Science Society of Thailand The Academy-Research Council is the representative of the United States in the Pacific Science Association, which is responsible for the Pacific Science Congresses Scientists and representatives of institutions in the United States are invited to participate A symposium on humid tropics research with special reference to climate, vegetation, and land utilization in the humid tropics is planned General symposiums are also being planned on the following subjects geology and geophysics, meteorology, oceanography, zoology, entomology, botany, conservation, museums, crop improvement, animal improvement, chemistry in the development of natural resources, public health and medical sciences, anthropology and social sciences, and nutrition Information may be obtained from the Pacific Science Office, Academy-Research Council, 2101 Constitution Ave, Washington 25, D C

EXAMINATIONS AND LICENSURE

American Board of Anesthesiology *Part I* Various locations, July 19 Final date for filing application was Jan 19 American Board of Anesthesiology *Oral* Washington, Oct 28-Nov 1 Sec, Dr Curtiss B Hickcox, 80 Seymour St, Hartford 15

American Board of Dermatology *Written* Several cities, June 27 *Oral* Baltimore, Oct 11-13 Final date for filing application was April 1 Sec, Dr Beatrice Maher Kesten, One Haven Ave, New York 32

American Board of Internal Medicine *Written* Oct 21 *Oral* Chicago, May 27-29, Los Angeles, Sept 11-14 Final date for filing applications was Feb 1 Exec Sec, Dr W A Werrell, 1 West Main St, Madison 3, Wis

American Board of Neurological Surgery Examination given twice annually, in the spring and fall In order to be eligible a candidate must have his application filed at least six months before the examination time Sec, Dr Leonard T Furlow, Washington University School of Medicine, St Louis 10

American Board of Obstetrics and Gynecology *Part II* Chicago, May 15-25 Final date for filing application was Feb 1 Applications for certification, new and reopened, for the 1958 Part I examinations are now being accepted Deadline for receipt of applications is September 1 Sec, Dr Robert L Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio

American Board of Ophthalmology *Oral* New York, May 23-27, Chicago, Oct 7-11 *Written* January 1958 Final date for filing application is July 1 Sec, Dr Merrill J King, Box 236, Cape Cottage Branch, Portland 9, Maine

American Board of Orthopaedic Surgery *Part II* New York City, Jan 29-31, 1958 Final date for filing application is August 15 Sec, Dr Sam W Banks, 116 South Michigan Avenue, Chicago 3

American Board of Otolaryngology Chicago, Oct 7-11 Final date for filing application was in April Sec, Dr Dean M Lierle, University Hospitals, Iowa City

American Board of Physical Medicine and Rehabilitation *Parts I and II* New York City June 8-9 Final date for filing application was March 1 Sec, Dr Earl C Elkins, 200 First St, S W, Rochester Minn

American Board of Preventive Medicine *Aviation Medicine* Denver, May 9-11 Sec, Dr Thomas F Whayne, 615 North Wolfe St, Baltimore

American Board of Proctology *Oral and Written Parts I and II* September Sec, Dr Stuart T Ross, 520 Franklin Ave, Garden City, N Y

American Board of Psychiatry and Neurology New York, Dec 16-17 Sec Dr David A Boyd, Jr, 102-110 Second Ave, S W, Rochester, Minn

American Board of Radiology Washington, Sept 23-28 Final date for filing application is June 1 Within the near future a special examination for certification in Nuclear Medicine will be offered to diplomates in Radiology and Therapeutic Radiology Sec, Kahler Hotel Bldg, Rochester, Minn

American Board of Surgery *Part II* New York, June 10-11 Sec, Dr John B Flick, 225 S 15th St, Philadelphia 2

American Board of Urology *Written examination* Various cities throughout the country *Pathology and Oral Clinical* February 1958 Location not decided Exec Secretary, Mrs Ruby L Griggs, 30 Westwood Road, Minneapolis 16

Board of Thoracic Surgery *Written* Various centers throughout the country, September 1957, and the closing date for registration is July 1, 1957 Sec, Dr William H Tuttle, 1151 Taylor Ave, Detroit 2

GOVERNMENT SERVICES

AIR FORCE

School of Aviation Medicine—Construction has begun on the new 9-million dollar installation for the School of Aviation Medicine on the outskirts of San Antonio, Texas Civic leaders and Air Force officials will take part in a formal ground-breaking ceremony on May 10

The arrival of the first construction party climaxed more than a decade of planning by the Air Force The projected center, many times delayed, was first proposed officially in August, 1946 It was approved by the Congress, and funds for construction appropriated in July, 1952 The four units now under construction are the research institute, academic building, flight medicine laboratory, and shops In the research institute three floors will be devoted to the aeromedical library and laboratories In the one-story academic building there will be classrooms that will accommodate 700 students and an auditorium with a seating capacity of 400 The shops, which will fabricate instruments for research, will contain electronic equipment to analyze statistical data and a medical photographic laboratory

In the altitude building there will be atmospheric pressure chambers costing 2 million dollars—some for research, others to familiarize medical officers with conditions that may affect flyers in the higher altitudes The hospital originally planned has been omitted from the present construction, for reasons of economy Instead, the new 1,000 bed hospital at nearby Lackland Air Force Base will provide support to the school A closed-circuit television system, with a link to the Lackland hospital, will show to student officers in the school's own classrooms the treatment given by flight surgeons at the hospital

Now occupying more than 40 buildings at Randolph Air Force Base, mostly temporary structures built during World War II, the School of Aviation Medicine will have in the new plant at Brooks a most advanced institution for medical teaching and research

Air Force Reserve Plans Medical Units—The Air Force Reserve has announced plans for the activation in April of 10 medical units with facilities for 6,000 bed patients The medical units will be located at CONAC's Air Reserve Flying and Training Centers throughout the country

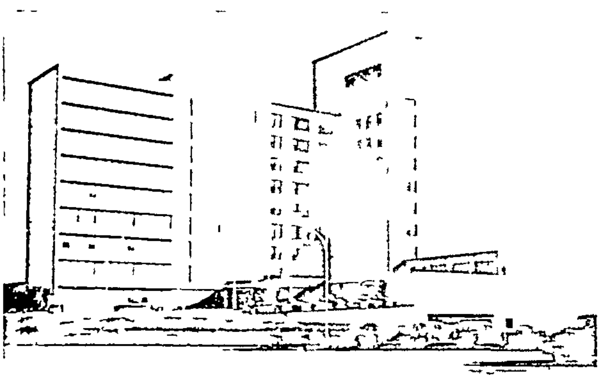
The new medical units will be manned by regular Air Force personnel and air reservists not on active duty from center location areas CONAC's Air Reserve centers will supervise the training of reservists assigned to the medical units Air Reserve personnel so assigned will be authorized the usual 48 training periods and 15-day active duty tours Training facilities for reserve medical units will be provided through joint use of CONAC's Air Reserve Centers or other U S Air Force or Defense Department installations

Eligibility requirements stipulate that individuals must be physically qualified for active military service Air Reserve officer personnel must meet age-in-grade requirements, however, this does not apply to reserve airmen Ready reservists desiring to be assigned to the medical units must have an AA availability classification code

ARMY

New Army Hospital at Fort Knox—The new $8,500,000 Merritte W Ireland Hospital at the Army Armor Center, Fort Knox, Ky, officially opened its doors for the first time April 1, when dedication ceremonies were held The guest speaker was the surgeon general of the Army, Major Gen Silas B Hays, who was introduced by the Fort Knox commander, Major Gen John L Ryan Jr The hospital was named after Major Gen Merritte Weber Ireland, who was surgeon general of the Army from 1918 to 1931 and a chief spokesman for Army medicine until his death in 1952

Among those present at the ceremonies were Mrs Merritte Ireland, Dr Paul Ireland, a son now practicing medicine in Ann Arbor, Mich, and grandsons, Capt Merritte W Ireland, a student at the U S Army Armor School, and Capt Paul M Ireland Jr, now stationed at Fort Leavenworth, Kan



The Merritte W Ireland Hospital

The Merritte W Ireland Army Hospital is a nine-story, 500 bed structure, planned so that two extra wings can be added, expanding the bed capacity to 1,000 It houses the latest hospital equipment and facilities About 25% of the hospital is air-conditioned Located outside the hospital is a parking lot with space for 535 cars

Army Intern Training Group—Army hospitals will welcome 164 graduates from 71 approved medical schools as interns for the year beginning July 1 This is the largest number of medical interns to be admitted at one time by the Army Medical Service since the establishment of such training These physicians will be commissioned as first lieutenants in the Medical Corps on entering the service, and, at the close of the one-year internship they will become captains if they remain in the service

The increase for 1957 is accounted for by the extension of intern training to the Army Hospital at Fort Benning, Ga It is planned to further expand these openings during the next few years through the addition of more hospitals to the program Seventy-three per cent, or 121, of the interns are married, 33 having one child, 21 having two children, 4 having three children, and 2 having four children The remaining 60 married interns have none

Hospitals that participate in the program are those approved for internship training by the Council on Medical Education and Hospitals of the American Medical Association

Three New Generals—Three new brigadier generals were added to the Army Medical Corps on March 25 1957 by the U S Senate They are Roger G Prentiss Jr surgeon at headquarters, 1st U S Army, Governors Island, New York, Paul S Franchner, commandant of Letterman Army Hospital at San Francisco, and Joseph H McNinch surgeon headquarters, U S Forces Far East

NAVY

Two Hundred Interns Selected for Training at Naval Hospitals—A total of 200 students who have graduated following the fall semester or who will be graduated at the end of the spring semester from medical schools throughout the United States and Canada have been selected to serve their internships at naval hospitals under the Navy s Graduate Medical Training Program Those selected will be appointed lieutenants (junior grade) in the Medical Corps and Naval Reserve and will be ordered to active military service The naval hospitals and the number of interns to be assigned are as follows

Chelsea Mass	12	Pensacola Fla	6
Newport R I	6	Great Lakes, Ill	12
St Albans L I N Y	20	Bremerton Wash	6
Philadelphia	18	Oakland Calif	20
Bethesda Md	20	Corona Calif	10

Charleston S C	6	San Diego Calif	28
Jacksonville Fla	6		

Lectures at the Naval Research Institute—Dr Gerhard Domagk professor of pathology, University of Munster Germany lectured at the Naval Medical Research Institute Bethesda Md March 26 on the present status of chemotherapy of tuberculosis Dr Domagk was in the United States on invitation of the New York Academy of Sciences, where he lectured on Twenty-five Years of Sulfonamide Therapy' Dr Domagk won the Nobel Prize in 1939 for his work on the action of sulfonamides on acute bacterial infections——Dr Marshall Brucer chairman, medical division, Oak Ridge Institute of Nuclear Studies in Tennessee, spoke March 7 on Clinical Radiation Dosimetry' at the Naval Medical Center in Bethesda

PUBLIC HEALTH SERVICE

Cooperative Research on Apoplexy—A nationwide cooperative research attack against cerebral vascular disease was announced April 2 by the surgeon general Ten medical research centers in nine states have already joined in the program, and it is expected that many more will ultimately participate, the surgeon general said The program, which is expected to run five or six years, is under the auspices of the National Institute of Neurological Diseases and Blindness, of which Dr Pearce Bailey is director

The new cerebral vascular research program was made possible by institute grants totaling $172,000 to the participating organizations The grants were recommended by the National Advisory Neurological Diseases and Blindness Council earlier this month The cooperative program is supplemented by 29 current individual projects directed to research on various aspects of cerebral vascular disease and supported by institute grants totaling about $250,000

These investigations will make possible the study of many patients who either have suffered a stroke or who show clinical signs indicating that a stroke might be coming on The results, it is said, are expected to shed new light on the nature and causes of strokes and to open the way to more effective treatment methods Another aim of the program is to make possible the more accurate selection of stroke patients most likely to benefit from surgical or nonsurgical therapies Data collected will be collated and evaluated at the University of Iowa, Iowa City, one of the cooperating institutions

Appoint Advisory Committee on Medical Practice—Surgeon General Leroy E Burney has announced the appointment of a committee of physicians to advise him on Public Health Service activities which are related to the practice of medicine The first meeting of the new Advisory Committee on Medical Practice Relations was held on April 4-5 in Washington, D C

We have many groups who advise us on research and disease control programs," Dr Burney said With the growth of medical and related research, it is increasingly important that we work with private physicians as well as with health agencies, to help apply the new knowledge promptly and effectively" Members of the advisory committee are Drs Stuart Adler, Albuquerque, N Mex , C Byron Blaisdell, Asbury Park, N J , Hugh H Hussey, Washington, D C , W L Potteus, Franklin, Ind , Julian P Price, Florence, S C , Stanley R Truman, Oakland, Calif , and William B Walsh, Washington, D C

More Grants for Research Facilities—The Public Health Service announced on March 30 the approval of 35 grants totaling $3,974,943 to help 27 research institutions in 18 states build additional facilities for research in cancer, heart disease, mental, and other major illnesses The grants were approved by the surgeon general on recommendation of the National Advisory Council on Health Research Facilities

The council, which met March 18-20, reviewed 165 applications amounting to about $66,384,500 Applications for grants will again be considered by the council May 27-29

Congress last year authorized 30 million dollars in grants a year for three years to research institutions on an equal matching basis for the construction and extension of research facilities The law also established the Health Research Facilities Council, which now has approved 109 grants totaling approximately 30 million dollars

DEATHS

Gomori George ⊕ Palo Alto Calif , born in Budapest, Hungary, July 16, 1901, Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultása Budapest, Hungary, 1928, specialist certified by the American Board of Pathology, member of the Illinois State Medical Society, College of American Pathologists, American Society for Experimental Pathology and the American Society for Clinical Pathologists which in 1955 presented him with the annual Ward Burdick Award for his contribution to the subject of histochemistry, served as president of the American Histochemical Society, formerly professor of medicine at the University of Chicago The School of Medicine, served on the staff of the Albert Merritt Billings Hospital in Chicago served on the board of editors of the *American Journal of Clinical Pathology* consultant to the Armed Forces Institute of Pathology, in 1941 coexhibitor with Dr Charles Huggins of Chicago, at the meeting of the American Medical Association and received a certificate of merit for an exhibit illustrating phosphatases and carcinoma of the prostate gland, died Feb 28, aged 52

McMurray, Carl Seifried ⊕ Nashville Tenn , born July 25, 1896 Vanderbilt University School of Medicine, Nashville, Tenn , 1917, assistant professor of clinical gynecology at his alma mater, where in 1918 he joined the faculty as assistant in surgery subsequently serving as instructor in surgery and instructor in clinical gynecology, professor of gynecology at the Meharry Medical College, member of the Southeastern Surgical Congress, Nashville Academy of Medicine, of which he was past president, and the Endocrine Society, past president of the Nashville Surgical Society, member, board of directors Tennessee Division, American Cancer Society, fellow of the American College of Surgeons, member of the Selective Service Board of Appeals, Middle Tennessee Judicial District since 1955, member of the staff and chairman of the tumor clinic, Nashville General Hospital, member and formerly chief of staff, Mid-State Baptist Hospital, on the staff of St Thomas Hospital, where he died Jan 18, aged 60, of rheumatic heart disease stenosis and calcification of aortic valve and pulmonary edema

Lamb, Frederick Howe ⊕ Davenport, Iowa, born in Fredonia, Pa , Sept 11, 1888, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1914, a founder, from 1936 to 1945 vice-president, and for many years an examiner of the American Board of Pathology, past president of the Iowa Clinical Pathological Society and Scott County Medical Society, a founding fellow and past president of the American Society of Clinical Pathologists, in 1956 received a scroll of recognition from that organization for originating the 'slide seminars," a high point in the annual meeting of that organization, founding fellow and past president of the College of American Pathologists, a director of the Davenport Bank and Trust Company, director of the clinical and pathological laboratories at Moline (Ill) Public Hospital, St Anthony's Hospital in Rock Island, Ill , and the Mercy Hospital, director of the clinical and pathological laboratories at St Luke s Hospital, where he was past president of the staff, and where he died Jan 25, aged 68, of cerebral hemorrhage

Hamilton, Joseph Gilbert, San Francisco, born in Waverley, Mass , Nov 11, 1907, University of California School of Medicine, San Francisco, 1936, research professor of experimental medicine and radiology at his alma mater, where he was director of the Crocker Radiation Laboratory, a member of numerous honorary medical societies, among them the American Physical Society, the Society for Experimental Biology and Medicine, American Society for Clinical Investigation, Sigma Xi, Tau Beta Pi, and Alpha Chi Sigma, medical consultant to the Atomic Energy Commission s division of biology and medicine and a member of the Atomic Energy Commission's committees on radioactive isotopes and the human application of radioactive materials, member of the National Research Council, chairman of the radiobiology study section of the National Institute of Health and a consultant to the Army and Navy, died in the Children s Hospital Feb 18 aged 49, of leukemia

Laage, Herbert August ⊕ New York City, born in Niendorf, Germany, May 31, 1907, Long Island College of Medicine, Brooklyn, 1932, clinical assistant professor of orthopedic surgery at his alma mater, now known as the State University of New York College of Medicine, specialist certified by the American Board of Orthopaedic Surgery, member of the American Academy of Orthopaedic Surgeons and the Industrial Medical Association, fellow of the International College of Surgeons and the American College of Surgeons, president of the medical staff at the Misericordia Hospital, where he was chief, department of orthopedics, and outpatient department, on the staffs of the Long Island College Hospital, Brooklyn, Eastern Long Island Hospital in Greenport, Central Suffolk Hospital, Riverhead, and the Good Samaritan Hospital in Suffern, died Feb 17, aged 49, of heart disease

Milch, Eugene Chandler ⊕ New York City, born in New York City, Aug 6, 1902, University of Virginia Department of Medicine, Charlottesville, 1927, specialist certified by the American Board of Psychiatry and Neurology, member of the American Psychoanalytic Association and the American Psychiatric Association, formerly instructor in neurology at the University and Bellevue Hospital Medical College, served on the faculty of Columbia University College of Physicians and Surgeons, lecturer in psychiatry at the State University of New York College of Medicine, Brooklyn,

---

⊕ Indicates Member of the American Medical Association

veteran of World War II, served on the staffs of the Mount Sinai and Beth Moses hospitals, from 1935 to 1940 assistant clinical psychiatrist of the New York State Psychiatric Institute died Jan 8, aged 54, of cancer

Barer, Charles Gregory Bronxville N Y born in Iowa City, Aug 11, 1904, State University of Iowa College of Medicine, Iowa City, 1928, specialist certified by the American Board of Ophthalmology, member of the Medical Society of the State of New York, veteran of World War II, served on the faculty of Columbia University College of Physicians and Surgeons in New York City and at his alma mater, on the staffs of the Institute of Ophthalmology of Presbyterian Hospital, Columbia Presbyterian Medical Center, and consultant in opthalmology at the Veterans Administration Hospital in New York City, staff member of the Lawrence Hospital, deputy fire chief, died Feb 8, aged 52, of ruptured dilated aorta

Kilbourne, Burton Kane * Hardin, Mont , born in Minneapolis Kan May 21, 1879, Kansas Medical College, Medical Department of Washburn College, Topeka 1904, formerly associated with the Kansas State Board of Health, a full-time city health officer in Fargo, N D , and epidemiologist of the Montana State Board of Health, served as state health officer and consultant for the state health department resigned in December, 1956 as full-time district health officer of Big Horn and Rosebud counties, served as secretary of the Montana Public Health Association, died in St Luke's Hospital Fargo, N D , Jan 20, aged 77, of cancer

McLellan, Philip Garretson * Hartford, Conn born in Caribou, Maine, Feb 28, 1900, Harvard Medical School, Boston, 1925, certified by the National Board of Medical Examiners, specialist certified by the American Board of Surgery, fellow of the American College of Surgeons, veteran of World War II, on the staff of the Hartford Hospital, consultant, Manchester (Conn) Hospital, New Britain (Conn) General Hospital, Institute of Living, Hartford, Windham Community Hospital, Willimantic, State of Connecticut Veterans Hospital, Rocky Hill, and the Veterans Administration Home and Hospital in Newington, died Jan 22, aged 56

Bracey, Lewis E, ⊕ Sheridan, Mich, Detroit College of Medicine, 1905, past village president and past school board member, served on the staff of the Kelsey Hospital in Lakeview, died Jan 20, aged 84, of cardiovascular disease

Butt, Charles Colwell ⊕ Nelsonville, Ohio, Medical College of Ohio, Cincinnati, 1909, health commissioner of Nelsonville and Yorkship health officer for many years, on the staff of Mount Saint Mary's Hospital, where he died Jan 14, aged 70, of cancer

Cables, Henry Albert ⊕ East St Louis, Ill, St Louis University School of Medicine, 1903, died Feb 13, aged 87

Carroll, Stevan Melton Jr ⊕ Marietta, Ga, Emory University School of Medicine, Atlanta, 1952, interned at the Grady Memorial Hospital, where he served a residency, member of the American Heart Association, veteran of World War II, instructor in pediatrics at his alma mater, chief of pediatrics at the Kennestone Hospital, killed Jan 24, aged 31, of injuries received when his automobile was struck by a train

Christensen, John F ⊕ Boulder, Colo, John A Creighton Medical College, Omaha, 1909, member of the Washington State Medical Association, on his retirement honored for long service as physician to Kelso (Wash) High School athletic teams, for many years president of the board of Cowlitz General Hospital in Longview, Wash, died Jan 28, aged 76, of coronary thrombosis

Clifton, John Lester Jr, ⊕ Columbus, Ohio, Ohio State University College of Medicine, Columbus, 1933, member of the American Academy of General Practice, on the staffs of the Grant and Mount Carmel hospitals, and the White Cross Hospital, where he died Jan 24, aged 48, of cancer

Cliver, Paul Mitchell, Laguna Beach, Calif, the Hahnemann Medical College and Hospital, Philadelphia, 1907, fellow of the American College of Surgeons, served on the faculty of his *alma mater*, formerly practiced in Chicago, died March 3, aged 77, of cerebrovascular accident and arteriosclerosis

Collins, Joseph Daniel ⊕ Northampton, Mass, Harvard Medical School, Boston, 1910, member of the American Academy of Ophthalmology and Otolaryngology, veteran of World War I, on the staffs of the Veterans Administration Hospital, Northampton State Hospital, and the Cooley Dickinson Hospital, where he died Jan 13, aged 75, of coronary thrombosis arteriosclerosis

Collins, D Bruce, Waurika Okla, Vanderbilt University School of Medicine, Nashville, Tenn, 1900, an associate member of the American Medical Association, formerly medical director of the Waurika Hospital which he owned retired surgeon for the Rock Island Railroad, died Feb 2 aged 77 of cancer

Combs Henry Burris, Bastrop Texas, University of Nashville (Tenn) Medical Department, 1892, Vanderbilt University School of Medicine, Nashville, 1892, died in Kerrville, Texas Dec 20 aged 85

Conlon, Philip Jerome ✠ Newark, N J, University of Pennsylvania School of Medicine, Philadelphia, 1910, served during World War I and was awarded the Croix de Guerre with two stars and the Distinguished Service Cross, on the emeritus staff, Harrison S Martland Medical Center, served on the surgical staffs of St Marys Hospital in Orange, and St Michaels Hospital, where he died Feb 7, aged 74 of cerebral hemorrhage

Cornfeld Morris, Philadelphia, University of Pennsylvania Department of Medicine Philadelphia, 1908, on the staff of the Albert Einstein Medical Center, an associate member of the American Medical Association, died Feb 13 aged 70 of gastric cancer

Cummings, Glenn C ✠ Rochester, N Y, University of Buffalo School of Medicine 1927, local examining physician for inductees during World War II, member of the Rochester Academy of Medicine and the Rochester Pathological Society, fellow of the American College of Allergists on the staff of the Genesee Hospital died Feb 5 aged 56 of coronary disease

Currie, Angus Bliss ✠ Groveton Texas (licensed in Texas under the Act of 1907), died Dec 28 aged 78

Davis George Washington, Ottawa Kan University Medical College of Kansas City Mo, 1896 veteran of World War I county health officer, died Jan 26 aged 88 of acute pulmonary edema

Davison, Seward Roland, Johnstown Pa, Jefferson Medical College of Philadelphia, 1905, an associate member of the American Medical Association, on the staff of the Conemaugh Valley Memorial Hospital, where he died Jan 15 aged 76, of cerebral thrombosis arteriosclerosis, and pyelonephritis

Deppe, Arthur H ✠ St Louis Washington University School of Medicine, St Louis, 1910, specialist certified by the American Board of Psychiatry and Neurology veteran of World War I, on the staff of the Evangelical Deaconess Home and Hospital, where he died Jan 17, aged 68, of arteriosclerotic heart disease

Dotterrer, Charles Brower, Boyertown, Pa, Medico-Chirurgical College of Philadelphia, 1902, formerly city councilman, veteran of World War I, died Jan 22, aged 77, of chronic myocarditis

Ervin, Humphrey Newton, Colonel, U S Army, retired, Springfield, Va, Ohio-Medical College of the University of Cincinnati, 1912, service member of the American Medical Association, veteran of World War I and II, entered the regular army Sept 8, 1920, retired March, 1947, returned to active duty from April 1, 1947 to Oct 4 1947, died Jan 6, aged 73

Evans, John Grant ✠ New Hartford, Iowa, State University of Iowa College of Medicine, Iowa City, 1893, formerly mayor of New Hartford and school board member, on the staffs of the Sartori Memorial Hospital in Cedar Falls, and Allen Memorial and St Francis hospitals, for many years surgeon for the Illinois Central Railroad died Jan 10 aged 90 of cerebral arteriosclerosis

Flynn, James Graham, Houston, Texas, University of Texas School of Medicine, Galveston, 1907, veteran of World War I, member of the Texas Medical Association, fellow of the American College of Surgeons, clinical professor of surgery at Baylor University College of Medicine, on the visiting staffs of the Methodist and St Joseph's hospitals, consultant, Hermann and Memorial hospitals, died in the Hermann Hospital Jan 31, aged 71

Fox, John W, St Petersburg, Fla, Detroit College of Medicine, 1897, died Feb 7, aged 85, of coronary occlusion

Franklin, Isidor Harold ✠ Jersey City, N J, Columbia University College of Physicians and Surgeons, New York City, 1912, veteran of World War I, on the staff of the Jersey City Medical Center, president emeritus and chairman of the board, Fairmount Hospital, died Jan 26, aged 66, of pneumonia and cardiac failure

Japhe, Nathaniel Michel, Mays Landing, N J, Long Island College Hospital, Brooklyn, 1926, member of the Industrial Medical Association, served on the staff of the Sydenham Hospital in New York City, died Dec 27, aged 52, of coronary occlusion

Johnson, David Ferdinand, Chunky, Miss, College of Medical Evangelists, Loma Linda and Los Angeles, 1937, certified by the National Board of Medical Examiners, served during World War II, formerly on the staff of the Madison Sanitarium and Hospital, Madison College, Tenn, died Feb 22, aged 52

McCann, William George ✠ Upper Darby, Pa, Hahnemann Medical College and Hospital of Philadelphia, 1949, veteran of World War II, later a captain in the U S Naval Air Force Reserve, on the staffs of the Thomas M Fitzgerald Mercy Hospital in Darby and the Hahnemann and Misericordia hospitals, died Jan 31, aged 31, of viral hepatitis

McCartney, Oliver Perry, Cheyenne, Wyo, Gross Medical College, Denver, 1901, veteran of World War I, died Jan 7, aged 87

McElligott, Joseph Arthur ✠ Milwaukee, Marquette University School of Medicine, Milwaukee, 1931, interned at Mercy Hospital in Oshkosh, at one time assistant superintendent of the Northern Hospital for the Insane in Winnebago, for many years physician with the maternal and child health bureau of the city health department, died Dec 21, aged 54

McMahon, Francis Joseph, Oteen, N C, St Louis University School of Medicine, 1925, on the staff of the Veterans Administration Hospital, service member of the American Medical Association, veteran of World War II, died in Rappolo, Italy, Jan 1, aged 57, of pulmonary emphysema and myocardial insufficiency

Mendel, Ernest, New York City, Ludwig-Maximilians-Universitat Medizinische Fakultat Munchen, Bavaria, Germany, 1920, member of the Medical Society of the State of New York, died in the Wickersham Hospital Jan 18, aged 61

Merchant, John Crapo, Nassau, N Y , Albany (N Y) Medical College, 1903, died in Essex Junction, Vt , Jan 14, aged 84

Miller, James Edison, Lieut Commander, U S Navy, retired, Acampo, Calif , Chicago College of Medicine and Surgery, 1916 entered the U S Navy in 1918, retired Nov 1, 1934, service member of the American Medical Association died Jan 5, aged 66

Muench, William George, Syracuse, N Y , Bellevue Hospital Medical College, New York City, 1898, an associate member of the American Medical Association, past president of the Academy of Medicine of Syracuse, for *many years physician to the Franciscan* Fathers, on the staff of St Joseph's Hospital, where he died Jan 9, aged 82, of congestive failure

Northrup, Laurance Curtis ⊕ Tulsa, Okla , University of Nebraska College of Medicine, Omaha, 1919, fellow of the International College of Surgeons, at one time county physician, member of the staff of the Hillcrest Medical Center, died Jan 24 aged 63, of cerebral thrombosis

Owensby, Oscar Monroe, Linden, Ala , Ensworth Medical College, St Joseph, Mo , 1909, formerly on the staff of the Mount Carmel Hospital in Pittsburg, Kan , veteran of World War I, died Dec 26 aged 74, of coronary thrombosis

Pierson, Frank F ⊕ Wilmington, Del , Hahnemann Medical College and Hospital of Philadelphia, 1891, draft examiner during World War I, once president of the staff of the Memorial Hospital, formerly known as the Homeopathic Hospital, which he originally joined, died Jan 23, aged 87, of carcinoma of the stomach

Poole, Lewis Roy ⊕ Easley, S C , Medical College of South Carolina, Charleston, 1925, member of the American Academy of General Practice, at one time health officer of Dothan, Ala , veteran of World War II, on the staff of the Greenville General Hospital, where he died Jan 9, aged 57, of carcinoma of the lungs with metastases

Powell, Charles M , St Louis, Meharry Medical College, Nashville, Tenn , 1910, died Dec 7, aged 84

Ray, Earl Bryning ⊕ Bellflower, Calif , College of Medical Evangelists, Loma Linda and Los Angeles, 1929, certified by the National Board of Medical Examiners, member of the American Academy of General Practice, veteran of World War II, served as chief of staff at Long Beach (Calif) Community Hospital, on the staffs of the Downey (Calif) Hospital and the Bellwood General Hospital, died Jan 5, aged 59, of coronary thrombosis

Renz, Herman Armand ⊕ Chicago, Hessische Ludwigs-Universitat Medizinische Fakultat, Giessen, Hesse, Germany, 1907, on the staff of the American Hospital, died Feb 15, aged 76, of carcinoma of the lung

Rockett, Fred William Boyd, San Antonio, Texas, Baylor University College of Medicine, Dallas, 1911, member of the American Academy of General Practice, died Oct 9, aged 70

Taylor, Paul James, Philadelphia, Jefferson Medical College of Philadelphia, 1906, died Nov 16, aged 82

Thompson, George W , Mount Vernon N Y , Howard University College of Medicine, Washington, D C , 1904, died in the Mount Vernon Hospital Jan 13, aged 84

Thompson, Ross W , Erie, Pa , Western Pennsylvania Medical College, Pittsburgh, 1902, an associate member of the American Medical Association, veteran of World War I, died Jan 6, aged 79, of coronary thrombosis

Tillotson, Joseph Elmer ⊕ Colusa, Calif , Columbia University College of Physicians and Surgeons, New York City, 1929, certified by the National Board of Medical Examiners, fellow of the American College of Surgeons, for many years surgical director of the Colusa Memorial Hospital, died in the Mercy Hospital, Sacramento, Jan 21, aged 53, of injuries resulting from an automobile accident

Williams, Carl Alonzo ⊕ St Petersburg, Fla , Hahnemann Medical College and Hospital of Philadelphia, 1895, past-president and for many years member of the Florida State Board of Medical Examiners, for many years practiced in New London, Conn , and in Worcester, Mass , died in the Lawrence and Memorial Associated Hospitals, New London, Conn , Dec 24, aged 84, of arteriosclerotic heart disease and popliteal aneurysm

Williams, John Wesley, Ingomar, Miss (licensed in Mississippi in 1908, died in the Shands Hospital, New Albany, Jan 21, aged 86

Woodward, Mortimer Lee ⊕ San Angelo, Texas, University of Tennessee College of Medicine, Memphis, 1922, died in Lampasas Dec 6, aged 71

Yazel, Herman Eugene ⊕ Kansas City, Mo , Ensworth Medical College, St Joseph, Mo , 1907, member of the American Academy of Ophthalmology and Otolaryngology, served in France during World War I, died in the Trinity Lutheran Hospital Jan 19, aged 76, of cerebral hemorrhage, arteriosclerosis, and diabetes mellitus

Young, Ruth Marie ⊕ Sharples, W Va , University of Pennsylvania School of Medicine, Philadelphia, 1951, served an internship at the Hospital of the University of Pennsylvania in Philadelphia, certified by the National Board of Medical Examiners, president and formerly secretary of the Boone County Medical Society, died Feb 9, aged 30, of asphyxiation and burns suffered during a fire, apparently caused by smoking in bed

Young, Simon J ⊕ Kendallville, Ind , Harvey Medical College, Chicago, 1902, fellow of the American College of Surgeons, served on the staff of the McCray Memorial Hospital, died Jan 13, aged 88

FOREIGN LETTERS

BRAZIL

Eosinophilic Skeletal Granuloma.—Dr. Lamartine Paiva and co-workers (*Rev. Hosp. clin.* 11:388, 1956) reported on the treatment with corticotropin of eosinophilic granuloma in bones. In a total of 450,000 patients admitted to the hospital since it opened, there were 10 with xanthomatosis. These cases were classified as follows: five cases of eosinophilic granuloma of the skeleton, one fatal case of Letterer-Siwe's disease and four cases of chronic idiopathic xanthomatosis. Of these 10 patients 2 with eosinophilic granuloma were treated with corticotropin and one with chronic idiopathic xanthomatosis was treated with cortisone. The rest of the patients were treated by irradiation and operation. The 10 patients reviewed by the authors belong to a series of only 15 patients with xanthomatosis reported in the Brazilian literature between 1930 and 1954.

The new case of eosinophilic granuloma reported by the authors was that of a 3-year-old child with a purulent discharge from the left ear and an elastic bulging of the right frontoparietal region. Incision of this bulging yielded a purulent material supposedly from an infection of the scalp. With the tentative diagnosis of chronic cholesteatomatous mastoiditis of the right side a mastoidectomy was performed. Great destruction of the osseous tissues of the mastoid process was found, with exposure of the meninges and the lateral sinus, the cavity being filled by granulomatous tissue. Microscopy revealed a chronic nonspecific inflammatory process without signs of osseous neoplasm. Other laboratory tests failed to reveal any specific process. Roentgenograms showed osteolytic lesions of the right frontal, parietal and temporal bones. A biopsy specimen of the parietal lesion was found to contain eosinophilic granulomatous tissue. The patient was given a total of 210 units of corticotropin intramuscularly in 24 days. After a six-month interruption of the treatment, the patient was readmitted to the hospital in about the same condition as on his previous admission and the treatment was resumed; 2,710 units of the hormone was given in 128 days. A marked improvement was obtained, as demonstrated by roentgenograms taken two and four months after the patient's discharge from the hospital.

Translumbar Aortography in Urology.—Although the radiologic visualization of the abdominal viscera was introduced by R. Santos in France between 1925 and 1931, it was rarely, if ever, used in Brazil until recently. Dr. G. Campos Freire and co-workers (*Rev. paulista med.* 49:321, 1956) reported its use in a selected group of patients. It was not used on those with uremia, poor general condition, or an idiosyncrasy to iodine. It was used on those in whom (1) the diagnosis could not be made by routine methods, (2) the urologic diagnosis had been made but aortography was expected to give supplementary information, and (3) aortography could theoretically furnish useful information about renal function based mainly on the radiologic findings in the renal arteries. The authors' series consisted of 10 patients between the ages of 18 and 68 years (average, 28 years). One had a horseshoe kidney; one, a polycystic kidney; two, hematuria with a negative excretory urogram (hydronephrosis due to extrinsic ureteral obstruction with retroperitoneal organized hematoma in one and renal block by ureteral obstruction due to a tumor of the bladder in the other); two, unilateral hypertensive nephropathy (hypoplastic kidney in one and pyelonephritic contracted kidney in the other); one, a renal tumor; one, hydronephrosis, and two, retroperitoneal tumors (a lipoma in one and a cystic teratoma in the other).

The authors believe that the procedure is useful in the study of patients with unilateral kidney disease with hypertension (kidney disease unassociated with extreme cardiac decompensation), anomalies, and vascularization of kidney tumors. Above all, they emphasize the importance of the method in evaluating the reserve power of the kidney with obstruction. In some cases, they performed conservative operations on the kidney supported only by the vascularization seen by means of serial lumbar aortography. They emphasize also the value of the procedure in the study of retroperitoneal tumors.

Drainage of the Bile Ducts.—Dr. Plinio Bove and co-workers reported to the Associação Paulista de Medicina on surgical drainage of the bile ducts in a series of 348 patients. Comparing the results with different procedures, they pointed out the good results obtained with Kehr's sound, especially when the instrument is made of soft latex, and the poor results of transpapillary drainage. At first they used a longitudinal incision of the choledocus, but now they prefer a transverse incision. The fixation of the sound on the skin has the disadvantages that it may damage the duodenum and produce angulation of the choledocus during inspiration. The speakers' standard procedure consists of stitching the bed of the gallbladder to the sound, thus avoiding fixation on the skin. Indications for drainage include cholangitis, acute and chronic cholecystitis, perforation of the gallbladder, acute pancreatitis, and pseudocysts and tumors of the bile ducts. The serum bilirubin level, after an early increase, begins to fall about the 8th day and becomes low about the 20th.

DENMARK

Suicide Among Middle-aged Men.—*Nordisk medicin* for Jan. 3 quotes Danish investigations reported on at a recent life insurance congress. Up to the age of 50

The items in these letters are contributed by regular correspondents in the various foreign countries.

about half of all the deaths among men were due to accidents or suicides, and for those men between the ages of 30 and 40 suicide was numerically the most important cause of death, being responsible for 22% of all deaths, while accidents accounted for 19% These figures refer to the period 1951 to 1953, during which 43% of all the deaths among males between the ages of 10 and 20 years were due to accidents, while the corresponding figure for suicides was 7% Between the ages of 20 and 30, 34% of all the deaths were due to accidents and 19% to suicides Between the ages of 40 and 50, 10 5% of all the deaths were due to accidents and 14 5% to suicides In this last age group two other causes of death began to be prominent, with 23% of the deaths due to cancer and 19% to heart disease Accidents and suicides figured more prominently in the period 1951 to 1953 than in any earlier period during the past 30 years With traffic accidents largely responsible for the rise in the accident death rate, one might have expected this rate to be higher for men in towns than in the country, but in the period under review the accident death rate was about 30% higher in the country than in towns for men up to the age of 35, after 35, this inequality was reversed The suicide death rate, however, was much higher in towns than in the country For women, accidents and suicides caused comparatively few deaths

Prognosis of Fracture of the Femur —At a recent meeting of the Danish Surgical Society, Dr H Jensenius gave an account of a follow-up investigation of patients with fracture of the neck of the femur treated by osteosynthesis Of the 213 patients discharged from the hospital, 105 were still alive at least five years later A follow-up examination of 99 of these patients showed that 27 had developed necrosis of the femoral head, which in 3 was associated with pseudarthrosis In 18 patients the necrosis was total, and in 9 it was partial The necrotic head had collapsed in 20 In view of the age of the patients and the comparatively long observation period, the late mortality of 51% in this series of patients was not significantly greater than for the community as a whole at the same age When the material was split up so as to shorten the observation period and deal only with patients under the age of 75, the death rate exceeded the normal In 76% of the total, the ultimate result could be regarded as good, while in 16% there was moderate and in 8% severe discomfort In 67% of the patients with necrosis the results were poor Discussing the comparative merits of conservative and operative treatment in the light of the literature on the subject, Jensenius concluded that the operative treatment is preferable and that operative technique other than that followed in his hospital does not promise better results than his own

Sale of Vitamins —About 170 different vitamin preparations are on sale in Denmark Hitherto the position has not been quite clear with regard to whether they come under the apothecary law restricting the sale of certain drugs to duly qualified druggists or whether they may be sold over the counter in any shop In 1954, the government limited the sale of certain vitamin preparations to druggists The cudgels were then taken up by a grocer whose protest came up to the final court of appeal, which in January, 1957, decided in his favor This means that vitamin preparations may now be sold by grocers This judgment is not likely to be final, and decisions will yet have to be made drawing the line between vitamin preparations that act as drugs and vitamin preparations that are nothing more than articles of food An editorial in *Ugeskrift for læger* for Feb 14 reminds grocers that the court of appeal expects them to show a high sense of responsibility in this matter

Resistant Micrococci —A study of Micrococcus pyogenes var aureus has been published in book form by the *Dansk Videnskabs Forlag* It is a doctoral thesis, and its author, Dr Flemming Lund, has undertaken a comprehensive survey of the behavior of this organism in eight hospitals in Copenhagen He has tested its sensitivity to penicillin, streptomycin, chlortetracycline, oxytetracycline, and chloramphenicol Serving as controls were various persons not living in the hospitals During 1952 and 1953 cultures were taken from the nasal mucosa of 583 persons serving on hospital staffs In one hospital, 67% of the nurses were carriers of Micrococci, all of which were found to be penicillin-resistant and 44% of which were resistant to streptomycin and chloramphenicol The carrier rate varied somewhat in the different hospitals and according to whether the nurses were newcomers or had worked in the hospital for some time When 41 permanent Micrococcus carriers were examined, both while at work in the hospital and after a vacation of two to three weeks, the carrier rate was reduced from 100% to 35% and the penicillin-resistant strains from 77% to 33% A study of the use of chemotherapeutic drugs in the different hospitals suggested that the risk of the development of multiresistant strains of Micrococci rises with the degree of such use It would also seem that several Danish hospitals constitute a definite reservoir of resistant organisms, whose numbers are increased from new hospital infections The employment of broad-spectrum antibiotics has meant at present the development of totally resistant strains of Micrococci in several hospitals In Lund's opinion, *hospital infections with resistant Micrococci can best* be combated by prophylactic measures

FRANCE

Pharmaceutical Mixtures Assessed by Vestibular Chronaxy —G Mouriquand and co-workers (*Presse med* 65 6, 1957) had previously demonstrated the existence of two types of drugs as regards their action on vestibular chronaxy one type causing it to increase, and the other causing it to decrease The authors opposed the chronaxy-diminishing action of calcium glutamate to the chronaxy-elevating action of vitamins B_1 and C They thus achieved a chronaxial balance Storage in a tight container of this balanced mixture for about one year did not alter it nor did its du exposure to air On the other hand, the authors' vious experiments using solutions of thiamine hydrochloride and ascorbic acid had shown these to be markedly altered in their action on vestibular chronaxy after being in contact with air (elevating power changed to reducing power), but with no apparent modification of their therapeutic action. They observed that thiamine (simple or lyophilized) withstands this modification of the chronaxy by air better in the powdered form. It seems preferable, therefore, in the case of long storage, to use a fresh solution of the powder rather than an old solution.

Cardiac Surgery.—H. Laborit and co-workers (*Presse méd.* 65:81, 1957) summarize the biological principles on which they based their experiments in intracardiac surgery with the bloodless heart under artificial hibernation. Under normal body temperature, facilitated by a massive supply of dextrose, the heart usually may be resuscitated after a circulatory arrest of 15 minutes' duration. The metabolic depression due to hypothermia and general anesthetics seems to make resuscitation difficult by preventing the discharge of sodium from the cell and the reintegration of potassium. This concept prompted the authors to reduce the sodium level during hypothermia and to increase the potassium level keeping it only relatively low in spite of the various hypokaliemia inducing factors (neuroplegics insulin and dextrose). At body temperatures they increase the concentration of carbon dioxide in the inhaled gases, with a view to favoring the dissociation of oxyhemoglobin whereas, up to 25 C (77 F), on the contrary hyperventilation facilitates the elimination of sodium. Cardiac and pulmonary resuscitation following a clamping of 25 to 41 minutes' duration and right ventriculotomy is rendered possible by giving hypertonic dextrose, clamping the descending thoracic aorta, and electric defibrillation. Of 22 animals operated on at temperatures between 15 and 22 C (59 and 71.6 F), 14 survived more than two days and 8 that survived for a shorter period might have been saved by better postoperative treatment.

Neuromuscular Excitability.—M. Albeaux-Fernet and co-workers (*Presse méd.* 65:61, 1957) report that neuromuscular excitability, as studied in relation to the duration and intensity of an electric stimulus, depends on the adrenals. The excitability varies in relation to such local anatomic factors as thickness of the skin, subcutaneous edema, and increase of the panniculus adiposus. Such nervous and muscular disorders as alcoholic polyneuritis, paraplegia, and monoplegia produce typical modifications in excitability. Alterations in excitability due to endocrinometabolic factors depend on the potassium level, but not exclusively. Hypoexcitability results from exogenous hypercorticism following treatment with corticoids, the endogenous hypercorticism of adrenal cortical hyperfunction (Cushing's syndrome) with its negative potassium balance and hyperexcitability results from hypercorticism with potassium retention. Increase in potassium concentration does not indefinitely augment the excitability, potassium intoxication, exacerbations of adrenal cortical hypofunction, and massive overload of the muscle with potassium in the course of periodic paralysis tend to reduce excitability, just as does an extreme potassium depletion. There is a parallelism between the electrocardiogram and neuromuscular excitability, the latter being a delicate index of modifications in kaliemia and tissular metabolism of the potassium ion, the evaluation of which is clinically difficult. Myxedema is accompanied by a diminution in excitability of nerves and muscles. Hyperthyroidism may be associated with neuromuscular hyperexcitability.

Response of the Adrenal Cortex in Manic-Depressive Crises.—H. Faure and co-workers (*Presse méd.* 65:65, 1957) investigated the possible correlations between the response of adrenal cortex to stimulation with corticotropin and biological reactions subsequent to electric shock in manic-depressive crises. They attempted to show that this correlation may allow the prediction of the effects of electroshock therapy. Twelve patients with acute manic and depressed states were studied. Each patient received 25 mg. of corticotropin parenterally and subsequently a series of six electroconvulsive shocks. There was a true correlation between the biological responses of the adrenal cortex after the administration of corticotropin and the clinical results due to shock therapy. The patients who responded most abnormally, biologically, to corticotropin before the treatment and to electroshock during the treatment were those who showed the most favorable clinical result, and vice versa.

Experimental Hypothermia and Allergy.—Vukobratovic and Bata (*Presse méd.* 65:7, 1957) state that hypothermia produces a favorable and protective effect against phenomena induced by the action of those substances that release histamines. As a rule, in experimental animals the level of the plasma histamine following injection of a histamine-liberator during the course of hypothermia is lower than that in normal animals. Such experimental facts have a bearing on the use of artificial hypothermia in patients in whom there is an endogenous release of histamine (snake bite, stings of insects and arthropods, and opiate poisoning). When rats were injected with a dextran solution during induced hypothermia, they showed no external signs and their plasma histamine level did not rise so high as that of the control animals. In allergic patients in whom focal hypothermia is effected there is no intradermal reactions to histamine and allergens. Conversely, these reactions become positive under normal conditions of body temperature.

Antituberculous Activity of Sulfoniazide.—Barety and Choubrac (*Presse méd.* 65:21, 1957) report that sulfoniazide, a new antituberculous agent, acts as a molecule and not by the release of isoniazid. It is well tolerated. Of 31 tuberculous patients treated with this drug, 13 showed significant radiologic clearing of pulmonary lesions and clinical improvement. Only six were classed as therapeutic failures.

Splenic Infarcts.—R. Poinso and co-workers (*Presse méd.* 65:84, 1957) report that splenic infarcts are due to an obstruction by an embolus or a thrombus in the main stem or terminal branches of the splenic artery

They are characterized by sudden pain in the right hypochondrium, fever, and increasing splenomegaly They may be divided into those occurring in the course of (1) polycythemia vera and mitral stenosis and other cardiac diseases, (2) certain infections or parasitic diseases, (3) hemopathies, especially those associated with malignancy, and (4) thromboembolic diseases Pathologically they may be classified as red or white Massive primary infarcts, especially those seen in thromboembolic disease, begin with agonizing pain in the left hypochondrium and a rise in temperature The patient appears acutely ill The presence of a polymorphonuclear leukocytosis suggests a splenic abscess Secondary infarcts occurring in the course of cardiac disease are due to an embolus or splenic endothelitis The presence of a large spleen in a patient with mitral stenosis is always indicative of an infarct The death rate in patients with splenic infarction is about 40% The treatment is nearly always surgical

New Hypoglycemic Agent—At the meeting of the Medical Society of Hospitals in Paris, in January, Felix Ramond reported that he had discovered a nontoxic hypoglycemic drug that may be taken by mouth Having noticed that diabetes among natives of Morocco was sometimes cured by a mysterious powder, the composition of which was jealously guarded, he had been able to identify it as the powdered leaves from the avocado and determined that only dried leaves covered with Fungi Imperfecti had any power This mould is easy to produce and is without antibiotic power Given three times a day in 150 mg doses, it can effect a lowering in glycosuria within six days

Inoculation Trypanosomiasis—Gallais and Collomb (*Presse med* 65 155 1957) report that African trypanosomiasis, after a course of variable duration, ends in a severe encephalitis in which there is a contrast between the psychic, neuroendocrine disorders on the one hand and the absence of focal neurological signs on the other hand Clinical observation of the patient has revealed a natural psychic 'dissolution,' formerly sought as a treatment for schizophrenia For this reason the authors inoculated 23 severely psychotic patients, most of whom were schizophrenic, with Trypanosoma gambiense They concluded that, if the patients are closely observed, the method is not hazardous In some patients lasting cures were obtained after failure of other methods

Cancer of the Colon—J Delarue and co-workers (*Presse med* 65 2164, 1957) state that malignant tumors of the colon are profusely vascularized This is confirmed by the frequency of hemorrhages from the cancerous tissues The new-formed network does not show an anarchic irregular structure as generally believed Vascular trees as a clearly segmented structure may be seen These vascular trees are attached to an arterial pedicle directly connected to the peripheral vascular system, with arteriovenous anastomoses in the vicinity of the pedicle The modifications of the circulatory system in carcinomas should not be regarded as resulting from a mere reaction related to the disordered growth of the tumorous cells It would appear that the preexisting circulatory system plays a leading role in impressing on the growth of the neoplasm an arrangement quite different from that of normal tissues but one in which an "organoid" structure is to be found

Thromboelastography—Benhamou and Griguer (*Presse méd* 65 2157, 1957) state that thromboelastography is a simple and easy technique that is helpful in the study of hemophilia, hemogenia, congenital or acquired hypoconvertinemia, obstetric and surgical afibrinogenemia, arterial or venous thrombosis, hypocoagulability (either spontaneous or due to anticoagulants), cirrhosis, malignant hemopathy, and possibly all diseases associated with disorders of clotting The thromboelastograms from patients with hemophilia, hemogenia, and thrombophilic syndromes have a characteristic, immediately recognizable appearance Those of patients taking anticoagulants are also typical and give us a better understanding of the action of the anticoagulants When they are considered with the other coagulation tests they aid in the proper treatment of arterial or venous thrombosis

Neurological Manifestations in Acute Porphyria—In *La presse medicale* (2 2, 1957), Bonduelle and coworkers reported that acute porphyria is less rare than is thought Since 1951, they have observed seven patients with this disease, six of whom had polyneuritic forms The disease follows a cyclic course, with a preparalytic period characterized by severe digestive symptoms, insomnia, mental disturbances and urinary symptoms Paralysis appears between the 30th and 40th days and reaches its maximum intensity 5 to 10 days later Death from respiratory paralysis may occur If it does not occur within one to four weeks, a regression occurs that ends, after some months, in a complete recovery Bouts of mental and digestive symptoms may mask the regular cyclic evolution of the disease Although artificial respiration may improve the prognosis in patients with this condition, it is still a disease that threatens life

Intratubal Injections—Biet and Legros (*Presse med* 65 2197, 1957) report on the treatment of various lesions of the oviducts with antibiotics combined with uterotubal injections of hydrocortisone This treatment in patients with acute or subacute infection, including tuberculosis, prevented the formation of fibrosis, permitting reestablishment of tubal patency following tubal pregnancy, and reduced the number of operations for removing the painful tubal masses These results, however, can be obtained only when the treatment is applied early

INDIA

Glucose Tolerance Tests in Cholera—S Banerjee and co-workers (*Indian J M Res* 45 1, 1957) undertook a study of the utilization of dextrose by patients with cholera, since earlier reports by other authors on the blood sugar values of such patients were contradictory An intravenous glucose tolerance test was performed on 22 patients with cholera and on 8 with gastroenteritis as soon as the patients were admitted to the hospital and before any specific treatment was given. Inorganic blood phosphorus values were also determined before and after administration of dextrose. Most of the patients had initial hyperglycemia, but a few had normal blood sugar levels. After the intravenous injection of dextrose, the blood sugar values rose, but two hours after the injection they came down, in most cases, below the initial level. The inorganic phosphorus level of the blood was high in all patients, and there was no correlation between the blood sugar and inorganic phosphorus levels after the injection of dextrose. The authors recommend intravenous administration of dextrose in performing a tolerance test. The study showed that, in spite of hyperglycemia, these patients can utilize dextrose. The patients suffering from gastroenteritis behaved similarly, thus indicating that the changes in the blood sugar and inorganic phosphorus levels observed were not specific for cholera.

Malnutrition in School Children.—Nutrition surveys conducted by the Urban Health Center under the joint auspices of UNICEF and the Union Government revealed that many school children in India suffer from malnutrition. The results of these surveys will help to ascertain the correct diet for these children. Surveys carried on in West Bengal revealed that the diet of many school children was deficient in vitamin B complex. To obtain an idea of the nutritional status of the school children of an urban area in Calcutta, the survey covered 345 children between the ages of 6 and 12 years in a local school representing different economic levels. The most common deficiency found among the children was that of vitamins A and C and protein. About 23.5% of the children suffering from a deficiency of vitamin B complex had such disorders as decayed teeth and glossal ulcers. One of the most important points that came to light was the high incidence of various deficiencies among children who came from families of good economic status. These were attributed to the absence of a controlled diet and the freedom to consume foodstuffs from vendors and shops. Surveys carried out in other states revealed that in Bihar the children suffered from diseases resulting from vitamin A deficiency. In East Punjab, rickets and simple goiter were the most common manifestations of deficiency. In Orissa and Madhya Pradesh most children showed deficiency of one form or other.

Cooperative Milk Unions.—Plans for the development of the milk industry have been included in the second Five-Year Plan. These plans envisage 36 cooperative milk unions for the supply of milk to urban areas by procuring milk from surrounding villages, establishing colonies for milch cattle, large dairies for improving the milk supply to those cities, 12 cooperative rural creameries, and 7 milk-products factories, expanding existing dairies, and establishing milk boards.

Cerebral Tuberculoma.—B. Ramamurthi (*Indian Journal of Surgery,* Dec., 1956) states that in a series of 476 suspected intracranial tumors 15.1% were tuberculomas. Tuberculous infection of the nervous system is secondary to a primary focus elsewhere in the body and is probably hematogenic. Tuberculomas have usually been found in patients who are better nourished than most tuberculous patients. Most of them have occurred without the patient having had any previous history of tuberculous meningitis. About half the patients gave a history of pulmonary tuberculosis or contact with a tuberculous patient, and 25% showed evidence of tuberculosis elsewhere in the body. The diagnosis was presumptive, but in 80% of the patients it proved correct. Roentgenograms of the skull occasionally showed a calcified area, but this is not common. Roentgenograms of the removed specimens showed much more obvious calcification. The tuberculomas occurred either under the meninges or inside the brain substance. There was no definite plane of cleavage between the brain and the tuberculoma. Histologically giant cell systems were not encountered as often as in tuberculous lesions elsewhere in the body. They were commonest in the younger age group, the incidence declining with age. The tuberculoma occasionally ruptured into the subarachnoid space or the ventricles and set an attack of acute tuberculous meningitis. Indications for operation were (1) progressively increasing intracranial pressure, (2) neurological disability, and (3) absence of response to antibacterial agents. Total removal is possible and results of the operation were good when streptomycin was given preoperatively and postoperatively.

Reserpine and Diabetes.—Menon and Ramakrishnan (*Antiseptic,* Feb., 1957) state that psychic or physical trauma can accelerate the appearance of latent diabetes in a hereditarily predisposed person, especially in association with infection, obesity, lack of exercise, or excessive eating. Rauwolfia serpentina has found a useful place in the control of stress factors and of the agitation caused by emotions and also in the treatment of mental disorders. In view of its antistress properties, it was given to 24 patients with diabetes who were selected irrespective of their age and duration or severity of their condition but with regard to some definite psychic trauma or stress factor. A glucose tolerance test was made before starting the treatment. The patients were hospitalized and given the maximum-calorie diabetic diet. Blood sugar determinations were made every four days to ascertain changes in its level. Two tablets of 5 mg. each were given three times daily for a month. No other drug was administered during this period. No appreciable change was seen in the blood sugar level, except in two patients with juvenile diabetes whose level showed a definite increase. Urinary sugar remained the same in 17 patients and showed a significant reduction in the rest. Total urinary output and frequency of micturition were reduced in all but four. Polydipsia was also decreased. In 16 patients there was a definite sense of psychological well-being. No serious side-effects were noticed. This drug thus had no definite effect on the blood sugar level, but it may occasionally be used as an adjunct in selected cases associated with definite stress in view of the psychological improvement produced after its administration.

UNITED KINGDOM

Vaccination Against Poliomyelitis with Live Virus Vaccines—In the *British Medical Journal* on Jan 12, D S Dane and co workers report that they tested vaccines made from TN type 2 and SM type 1 attenuated poliomyelitis virus The first was found to be noncytopathogenic in monkey-kidney-tissue culture and to produce no paralysis when inoculated intracerebrally into monkeys Excreted fecal virus was found to be cytopathogenic and to cause severe paralysis when inoculated intracerebrally into monkeys The laboratory characteristics of attenuation shown by TN type 2 virus that made it appear suitable for trial as a vaccine are not maintained after multiplication in the human intestine The SM type 1 virus was shown to spread within a normal family living under normal conditions of hygiene after the vaccination of one child in the family SM fecal virus was found to cause paralysis in some monkeys inoculated intracerebrally, whereas monkeys inoculated by this route with SM vaccine virus were not paralyzed Although the TN and SM strains are not yet acceptable for mass immunization, this does not mean that suitable strains will not be developed The authors believe that the minimum requirements for an attenuated poliomyelitis vaccine are as follows 1 The vaccine virus and any excreted virus should be intracerebrally avirulent for monkeys and perhaps also intraspinally avirulent, intracerebral avirulence alone may be acceptable provided the other requirements are fulfilled 2 The virus should not be transmissible from vaccinated to nonvaccinated persons 3 It and any of its progeny that are excreted should have some marker that differentiates them from the naturally occurring wild strains of virus 4 It preferably should not multiply in the throat 5 It should prevent paralytic poliomyelitis in those who are susceptible (This may not require 100% antibody response in vaccinated persons)

Novel Cardiac Operation—An operation to remove a tumor of the heart was successfully performed at Southampton Chest Hospital It is believed to be the first successful operation of its kind The patient, a 25-year-old man, had a benign tumor in the left side of the heart He had been operated on 10 days earlier, but when the surgeon discovered the position of the tumor, he decided to close the incision and perform another operation later from the opposite side In previous operations throughout the world the approach to such a growth was made through the left side of the heart Such operations have always failed At Southampton the approach was made from the right side It meant that the septum between the left and right sides had to be opened and closed again after the tumor was removed The patient had complained two years earlier that he was subject to blackouts He has now made an uneventful recovery

The Breath in Acute Leukemia—Dr E K Blackburn (*British Medical Journal,* Jan 19, 1957) calls attention to a new clinical sign consisting of a peculiar sweet odor of the breath found in 73 patients with leukemia (51 acute and 22 chronic cases) It was present in 12 of the patients with acute leukemia without obvious clinical involvement of the gums, mouth, or upper respiratory and alimentary tracts In six of these, there were signs and symptoms, such as splenomegaly, to suggest the true diagnosis, while ordinary clinical examination of the other six (other than the finding of halitosis) was unrewarding, and only after examination of the blood and bone marrow could the diagnosis be confirmed

Monilial Vaginitis—In the *British Medical Journal* of Jan 19, Jennison and Llywelyn-Jones describe the results of a clinical trial on patients with monilial vaginitis treated with nystatin and also with gentian violet Of 53 women with the disorder treated by means of a new type pessary containing 100,000 units of nystatin, 47, or 88%, were free from infection one week after treatment Of 36 treated with gentian violet, only 17, or 47%, were cured Of a group of 18 who had not responded to gentian violet, 16 were cured with nystatin In the patients seen four weeks after treatment, the relapse rate was 46% in those treated with gentian violet and 21% in those treated with nystatin No side-effects or local discomfort occurred with nystatin, whereas six of the women treated with gentian violet had a reaction that made it necessary to stop treatment One patient was given nystatin only by mouth, with an apparent cure

Discrimination Against Physicians—A circular to hospital authorities states that the Minister of Health proposes to follow the recommendation of the Guillebaud Committee that medical membership of regional hospital boards should normally not exceed 25% and that he has asked the boards to do the same when making appointments to hospital management committees Special considerations apply to boards of governors where provision has to be made not only for nomination of members by the hospital medical staff but also for nomination by the university (whose nominees may also be medical) Nevertheless, the Minister asks that regional hospital boards should secure a reasonable balance of lay representation when making nominations for membership of boards of governors

Olympic Award—The International Olympic Com mittee has awarded the 1956 Fearnley Cup to the Stoke Mandeville Games in recognition of the outstanding services of the International Sports Movement for the Paralyzed to the Olympic movement The Fearnley Cup is awarded annually to a sports organization in some country, this is not only the first time the cup has been won by Great Britain, but also the first time it has been awarded to a sports organization for the disabled The International Sports Movement for the Paralyzed was the creation of Dr L Guttmann, director of the National Spinal Injuries Center Mandeville Hospital, Aylesbury At the first Stoke Mandeville Games in 1948 there were 16 competitors, all from Great Britain, by 1952 the Stoke Mandeville Games had become international At the 1956 games no fewer that 300 paralyzed competitors from 19 different nations participated

Heavy Fine on Physician Urged.—The Minister of Health has been asked to inflict a heavy fine on a Salford family physician who issued National Health Service prescriptions to private patients. He admitted to the local medical service committee that the irregular issue of health service prescriptions had been going on since the health service started in 1948. The committee took a serious view of the manner in which his practice had been conducted and concluded that it had been his policy to use the National Health Service for the retention of the private practice he had enjoyed before 1948. The medical service committee in Surrey recommended that another physician be censured and have $280 withheld from his pay. It reports that when a man fell and fractured his skull, this physician, living a mile and a half away, failed to attend him until nine hours later. By then the man had died.

Deaths from Poliomyelitis Among Physicians.—Doll and Hill have shown that physicians between the ages of 25 and 45 years are at special risk of dying from poliomyelitis (*Brit. M. J.* 1:372, 1957). There are nearly 10 times as many deaths from the disease among physicians in this age group as there are in the general population in the same age group. Physicians who die from poliomyelitis are relatively young. One possible explanation is that persons in the higher social classes have a greater chance of contracting poliomyelitis, although there is no statistical evidence to support this belief.

Physicians Seek Alternative Health Plan.—Many physicians contemplating their position in the light of the present pay dispute with the Minister of Health assert that the National Health Service in its present form is unacceptable. Attention is being directed to other schemes such as those in force in the Dominions. In Australia, for example, the individual contributes what he believes he can afford to a voluntary health insurance scheme. His contribution is matched by a similar payment from the government. Coverage for sickness depends therefore on the scale of the combined contribution. About 75% of the population subscribe to the plan. Those whose incomes are below a certain level receive free medical treatment. Evidence of dissatisfaction with the National Health Service is provided in letters from many physicians. One of these points out that the health service is defective because it fixes the physician's wages at $2.21 per patient for a year's treatment. Not a penny extra is paid for house calls, consultations, advice given in the middle of the night, or increased operating expenses. (To a certain extent the last-mentioned can be deducted from taxable income.) No other civil servant of equivalent salary with equivalent working hours must pay for the heating, lighting, equipping, cleaning, taxes, and maintenance of his office. In addition to these expenses, it is essential that physicians maintain automobiles. The taxes on physicians' offices have been doubled, yet these offices are all subject to inspection and should improvements be necessary the physician must make them and without tax relief. The National Health Service is full of such anomalies, which are not generally realized. With a fixed rate of payment and an increasing overhead, the more attentive the physician is to his patients the less profit he makes. The physician loves his profession, but he cannot live on love.

Physicians Dissatisfied with National Health Service.—In a two-hour meeting at the Ministry of Health, the representatives of 40,000 National Health Service physicians failed to persuade Mr. Turton, the Minister, to concede a pay increase averaging $28 a week. There will, however, be no immediate strike or other drastic action. The Minister asked the physicians to confer with him again later in February, and they agreed to do so. This show of patience came at the end of a session during which the physicians, in a fighting and determined mood, had not pulled their punches. When one of them suggested that the invitation to a further meeting might be another delaying tactic, the Minister assured the delegation that he was reviewing the issues involved. Presumably at the next meeting he will produce some plan, though he gave the physicians no inkling of what he had in mind. After nearly a year of negotiation, a further three weeks of unproductive delay would seem to be a futile proceeding. Sir Russell Brain, president of the Royal College of Physicians and leader of the deputation, said after the meeting with Mr. Turton: "This is not merely a pay claim but a crisis of confidence. It goes to the roots of the relations between the medical profession and the government." After the meeting, the Ministry of Health issued a statement to the effect that the claim is for an increase of not less than 24% over present levels of remuneration (which in the case of general practitioners is, on the average, already 137% above the prewar level). The extra cost to the country would be about 56 million dollars a year. The claim has not been rejected, but, since the government is responsible for doing everything possible to combat inflation, the claim is considered untimely.

In other words, the Minister avoided expressing any opinion on the merits of the claim. Furthermore, he denied the profession's contention that the government is under a legal contractual obligation. Local meetings of the British Medical Guild are now taking place all over the country. The guild would come into action on the directive of a special representative meeting. Such a meeting will not be called before the next talks with the Minister.

The Incidence of Diabetes.—With the help of local general practitioners, Andrews has surveyed a third of the population of Cornwall in order to obtain statistics on the incidence and treatment of diabetes (*Brit. M. J.* 1:427, 1957). The incidence was found to be 5.6 per 1,000 persons in a population of just over 250,000. It varied from 3.2 to 8.4 per 1,000 persons within the areas of practice surveyed. No significant difference was found in the rural and urban areas of practice. The incidence was greater than the generally accepted figure of 2.3 per 1,000 persons for the country as a whole. This figure was based on the Ministry of Food returns made 10 years ago when essential foods were rationed, and, therefore, it is not reliable. A recent general practice survey gave an incidence of 3 6 per 1,000 The sex distribution shows a preponderance of women, in whom the incidence of the disease is 1 7 times that in men The average age of onset in both sexes was 52 years, although it tended to occur earlier in men The classic symptoms (thirst, polyuria, and loss of weight) were the reasons for seeking medical advice in only 41% of the patients In most cases the diagnosis was made on the patient's admission to the hospital for illnesses unrelated to diabetes, or it was made by general practitioners making routine urine tests This suggests that many mild cases of diabetes remain undiagnosed

Seventy-seven per cent of the patients attend a general medical or diabetic clinic for supervision About 20% adhere to a strict dietary regimen Of those requiring insulin, 80% of the men and 62% of the women administered it themselves, those unable to do so sought the help of other members of the household or the district nurse The nurse visited 15% of all diabetics in a year and gave insulin to 6% Most of these diabetics were well controlled, as diabetes or its complications were responsible for only 15% of all days spent by the patients in bed The general practitioner saw the average diabetic 10 times a year, which was twice the average for the population as a whole, and he was consulted by 91% at some time during the year The commonest cause of admission of the diabetic to the hospital was for stabilization, although 42% of all admissions were for conditions not associated with diabetes Cardiovascular disease was responsible for death in more than half the patients followed up The average age at death of both sexes was 67 years

The Changing Pattern of Leukemia —Lea and Abbott, from an analysis of 624 cases of leukemia occurring in the armed forces between 1940 and 1955, concluded that the pattern of the disease is changing (*Lancet* 1 389, 1957) The disease was acute in 59% of all cases, with an increase in age of the patient at onset from 29 years in 1940 to 33 in 1955 In the same period the age of the patient at the onset of chronic leukemia fell from 34 to 33 years These changes were not due to an increase in the average age of members of the armed forces, there was actually a decrease from 28 7 years in 1940 to 23 9 years in 1955 This increase in the incidence of leukemia is attributed to increased exposure to radiation and to the use of sulfonamides after 1940 Lea and Abbott cite the increase in the use of diagnostic radiology in the western countries in the last half century

Fatigue in Nurses —As a result of complaints that nurses are overtaxed and overstrained, a committee representing all grades of nurses in training schools was set up in 1954 to investigate the problem In their report, now published, the committee states that much of the overstrain and fatigue in nurses has its origin in emotional and mental rather than in physical causes One overriding factor is that the nurse, unlike other students, is cut off from her home life and spends her whole time, both working and offtime in [illegible] community and in an atmosphere of sickness centered on the hospital The remedy for this the committee suggests, is for the nurse to live like an undergraduate in a hostel not associated with the hospital and to have university terms as any other undergraduate so that she can go home for vacations She should be on duty for regular hours, and her first year should be spent in lectures and ward work under supervision and with no responsibility The young nurse should be protected from some of the rigors of hospital work A questionnaire dealing with hours of work, meals, lectures, and other relevant information was sent to 5,284 nurses in the southwest area The replies showed that half the student nurses in general hospitals work overtime, either regularly or often, and that in mental hospitals all of them work overtime half of them regularly Over one-third of all student nurses have lectures in their off-duty time This is attributed to a shortage of staff The committee proposes that more should be done to recruit older women, trained or untrained, to nursing

No Poliomyelitis Vaccine —It now appears as if relatively few children are going to be vaccinated against poliomyelitis before the summer Last December the Ministry of Health announced that it was hoped that supplies of vaccine would be ready early in the new year, and instructions were issued to health officers accordingly Early in February the Ministry announced that one batch of vaccine had to be discarded, because it had become contaminated, and that another batch required further testing before it could be released Later in the month it was announced that a batch of vaccine should be ready the following week and health officers immediately started to make appointments for children to report for vaccination Five days later the Ministry announced that there would be a further delay, as there had been an inexplicable change in the pH of the vaccine resulting in a change of color What has aroused the greatest resentment is the way the Ministry has misled the public by its repeated announcements of the vaccine being available shortly and then having to announce a further delay The effect on the morale of parents has been dep[illegible] able, and, inevitably, doubts have arisen in the [illegible] mind as to the ability of our research workers [illegible] manufacturers to provide the vaccine What the [illegible] public is that [illegible] try has never made clear to the public when [illegible] possible to give a precise date when the [illegible] batch will be ready This point has [illegible] phasized by the manufacturers [illegible] upset than they that the Ministry [illegible] misleading statements to the [illegible] Ministry has not issued [illegible] It is being left to the [illegible] reassure the [illegible] the Ministry [illegible]

LAOS MEDICAL MISSION

To the Editor:—In the Sept. 1, 1956, issue of THE JOURNAL, page 38, my editorial telling of our projected medical mission to Laos was published. We have been here now for six months. I would like to thank the hundreds of doctors who have written and helped me and tell them something of what has passed, reference we four "Mekong Medicine Men."

Our mission has two ends. Because I am a doctor, my duty is to the people who need doctors. They are needed here. That is simple. The second end of our mission is to make a sober, honest effort to show Asians who have never seen an American just what four of us are like. This is not always so simple.

The minister of health of Laos is the only doctor in the kingdom, by international standards. When we arrived he asked me to set up the team in the village of Vang Vieng. This village is a hard eight-hour jeep trip north from the capital of Vientiane to the foothills of the Himalayas. In a valley you will find Vang Vieng cradled in the mountains, wrapped in the warmth of the tropical sun and covered by the bluest sky east of home.

We were given a small limestone one-story building. With much help from the villagers, a good deal of scrubbing, scouring, and painting we converted this into a hospital—after anastomosing it to a second building next door—with bamboo. Ours is a three-room 25 mat hospital (the classification of hospitals by bed capacity does not apply here). One room of the hospital is used as living quarters for our Lao nurses, the second room triples as an operating room, delivery room, and sick call room. The third room is the ward—with bamboo mats on the floor. This is not so difficult on the patient but it plays havoc on an Anglo-Saxon physician's back pain. There is a veranda connecting these three rooms on the outside. Over this hospital flies the American flag. And for the record, we have painted our hospital Kelly green. Down the path a half-mile we were given a hut-of-a-house-on-stilts. It is now cleaned up, it is roomy, comfortable, warm, kerosene lamp-lit—and also, Kelly green.

If the reader could put this journal down, grab a PAA plane and fly 10,000 miles to Bangkok, Thailand, transfer and fly 400 miles north to Vientiane, and then drive eight hours through the jungle to us—we would offer you a cup of coffee and ask you to spend the day with us. Our typical day starts at dawn or thereabouts. (No one knows the exact time, clocks are a curse of civilization and you left that in Vientiane—anyway, why spend your life strapped to the watch on your wrist?) After breakfast of fried eggs (yesterday's pay) we would walk down the path to the hospital. There are already over 50 people from this and surrounding villages, as well as a sprinkling of brightly clothed tribal people such as the Kha, the Meo, and the Yao.

We first hold rounds on the ward. One of my men, Peter Kessey, works here with two Lao nurses. Today we have several cases of malaria, a lacerated Achilles tendon repaired last week, and a charred third-degree burn of the back and buttocks. Then a variety of machete-inflicted wounds of the legs, as these people must hack their meager existence from a savage jungle. Unfortunately we usually have some obstetrics problems, and yesterday we admitted a young lad named Iong, who had been mauled by a wild boar. We have six cases of fulminating pneumonia, which I know will respond magnificently to Combiotic. You will see a few patients severely dehydrated due to their dysentery. We give them saline solution by vein, bouillon tea, and Terramycin by mouth. They do well. We have a few nutritional problems of assorted types, but those with the severest cases have massive edema and heart enlargement—kwashiorkor.

When rounds are finished, sick call begins. Norman Baker and Dennis Shepard, my two American corpsmen, help me. Three Lao nurses also assist. We always work through the Lao, as this increases their prestige and education, and keeps us from blundering too badly over such words as "chep hua" which can mean "headache" or "criminally insane." The long, sometimes dreary, line seems endless. There are always wizened old people spitting out their last days and the remainder of their pulmonary tissue—pleading for help—not much I can do but palliation. There are children with beriberi and other deficiency diseases—due only to ignorance, not famine. Many kids carry their fungous scabby sores like a dirty stocking cap. We always have a bucketful of cases of chronic progressive sloughing ulcers of the lower extremities. The quick response of these to penicillin and good nursing care makes the diagnosis of yaws or other spirochetes likely. There are cases of malaria, pneumonia, bronchitis, scabies, and arthritis by the dozens. Sometimes some rather esoteric diseases present themselves, such as a tingling over the right knee cap that rapidly leaps into the nostril, and is present only when the sun sets every night. But the sun just now is straight overhead. When morning sick call is finished we find that we have had 62 people treated.

We return now to our house, which my boys have entitled "Uncle Tom's Cabin." We lunch on C-rations, rice, and corn (the latter two grow here, the former a necessary horror developed by the U. S. Navy in the exigency of war—but, giving credit where it is due, six months of just this, with an occasional gin and tonic, has kept my team in fine fettle, though a bit low on subcutaneous fat).

After lunch we load up the jeep with medical boxes and drive on the trails into the surrounding mountains to treat tribes who could not get down to Vang Vieng in the morning. Two members of the team hold this off-the-jeep's-tail-gate clinic until the sun is about ready to set. The other team members hold the afternoon classes in Vang Vieng. We have three courses. One in the local school for 300 children on hygiene and sanitation. The second is for 15 girls who come from 15 different villages—we are training them to be midwives. The third class is for the villagers themselves and is entitled "community development." It covers such topics as baby care, proper cooking, washing, and latrine building. (Let me speak coprologically for the moment. Whatever the etiology or nomenclature for diarrhea and its accouterments—Gyppy tummy, Jordan jumps, Baghdad belly, Yangtze rapids, Saigon two step, the Runs, or Trots—this ailment is the greatest internationalist of us all. Grin not at the mention of latrines!) Our education program is extremely important. We do not want to be a crash hit-and run mission. When we leave this area we want to leave something behind us. This program will accomplish much of this.

All the team members usually get back to the house a little after sundown. Each then enters a hugh bamboo construction which supports a 60-gal. barrel and a kerosene heater. Though it looks like an illegitimate union between a Texas oil derrick and the leaning tower of Pisa, it is our "shower." Regardless of the starboard list, the water is hot and the need great. After dinner we show a movie either in Vang Vieng or in a nearby village. On alternate nights we play the accordion and just "mi yam" or "visit." "Fantasia," Mickey Mouse, Donald Duck, and Oklahoma and her natural resources are all loved, but Bambi has conquered this part of Southeast Asia.

Tomorrow is a surgery day so we go to bed early, but the night is usually an interrupted one (there are not many doctors anywhere who do not have this problem), however, night calls here plunge the doctor into humanity at its bleating, suffering, stinking best—terror, disease, hunger, misery, different from anywhere else.

As in America, the end of the day finds the doctor reviewing his patients. What they are doing. Are they following your orders? Yes, as in America, your patients here will be taking your medicines and rubbing in your ointments. In America the doctor's opinion frequently rules supreme—the stethoscope and American doctor's magic reign supreme here also—during the day. But at the fall of night necromancy is potent. Herbs, portents, malicious and beneficient spirits are called forth to catalize your penicillin. Monkey's blood is drunk. "Blessed" strings of cotton are tied around an aching part. The incantations of the Chinese medicine men or the local witch doctor can be heard. A sorcerer is feverishly rubbing cow dung and beetle juice on the child's chest while his parents are smoking a stinking tobacco and blowing the smoke into the youngster's ears. And around their hut the yaws patients are sitting with those with whooping cough, on the floor where the old men are spitting. The mother with pocked cutaneous ulcers is holding a baby who is being sick at both ends at the same time. Chicken feathers are being waved beneath the nose of a woman whose pregnancy is past term, and garlic grease is being smeared over a sore—perhaps it will help the doctor's bacitracin ointment.

When the morning comes and many are cured, the credit will be divided between the two magics, the new and the old. These poor people are thrust into the chasm that yawns between these two. You might think, as I do, that we Americans are worrying a bit too much about the people we want to liberate from the godless tyranny of communism and are ignoring those we could liberate from the tyrannies of ignorance and disease. Medicine can be used as a weapon of foreign policy, and that is what we four are trying to do.

GIN AND TONIC—A CAUSE OF DERMATITIS

To the Editor.—In recent years gin and tonic (quinine water) has become an exceedingly popular drink. To the old adage, "New drugs, new eruptions," we must now add a corollary: "New drinks, new eruptions." Many people do not tolerate quinine. Sensitivity to quinine may produce many reactions involving various tissues. For example, the eighth nerve reacts with tinnitus, deafness, and vertigo. Involvement of the optic nerve results in visual impairment with photophobia and diplopia. Headaches and fever are frequent manifestations of quinine idiosyncrasy. Dyspnea has been reported. The gastrointestinal tract can be involved, with resulting abdominal distress, nausea, vomiting, and diarrhea. By far the commonest tissue to react to this drug is the skin. The types of eruptions are many and varied. The mildest of these is a transient scarlatiniform of erythema. In addition to this, papular, vesicular, and even bullous eruptions have been described. The latter type of dermatitis can be very severe, and in some patients may even lead to death. A dose as small as 60 mg. of quinine may produce a severe systemic reaction.

We have seen a patient with a severe reaction that followed drinking quinine water. This 36-year-old man was admitted to the Samuel Merritt Hospital, Oakland, Calif., on June 7, 1955, because of a generalized eruption. On several occasions, in his childhood and in his teens, he had had a severe generalized eruption that he said was like scarlet fever, and he recalled that his attending physician had made that tentative diagnosis on several occasions. In his teens, he had a severe upper respiratory infection for which he was given some capsules, and he again developed a severe dermatitis. At that time, his physician told him that the capsules contained quinine and that he was sensitive to the drug. About 15 years ago he had a facial massage after which a toilet water was applied to his face. On the next day he developed a dermatitis with edema so marked that his eyes were closed, and lacrimation was profuse. It is possible that the toilet water contained quinine. Because the patient knew of his sensitivity to quinine, he had avoided drinking gin and tonic. On a number of occasions, however, he had imbibed various other gin drinks and had experienced no difficulty.

Two days before admission, he attended a cocktail party. The only type of drink served on this occasion was gin and tonic. During the course of three hours, he had five or six drinks Two hours later, he noticed a burning sensation in the groins and in his hands and feet This became worse as the evening progressed On the next morning he noticed edema and marked erythema in these areas In the next 24 hours the eruption spread to involve nearly all of his body Because of the extent and severity of the eruption, he was hospitalized

On admission he had a nearly universal dermatitis There was marked underlying edema so that the features of his face were masked There was marked swelling about his eyes Edema of his arms, legs, and feet was pronounced Superimposed on this was a brilliant erythema which in some areas assumed a purple hue There was vesiculation and weeping of the skin about his face On his back and trunk, in addition to the erythema, there were inflammatory papules, some of which had superimposed vesicles or fine pustules suggestive of a miliaria His palms and soles were covered with large bullae which coalesced in places to form large blebs His feet were more severely involved than his hands The patient had a temperature of 101 F (38 3 C) He was given colloidal baths followed by wet dressings of a 1 16 dilution of aluminum acetate solution, and a simple shake lotion was applied to the less extensively involved areas He was also given corticotropin intramuscularly and tripelennamine citrate by mouth On this regimen his condition improved, and he was discharged from the hospital after six days At the end of 16 days, the eruption had cleared entirely except for some fine scales about his hands and feet About two weeks later, a patch test was performed on the right upper portion of his back, using a 1% solution of quinine bisulfate, 15 drops (1 cc) was used to saturate a piece of gauze 1 cm square The patch was then removed in 48 hours, and the area showed a marked reaction, with a large bulla measuring 8 by 8 cm During the test, one drop ran down the patient s back and flank Along this line where the solution came in contact with the skin there was a streak showing erythema and vesiculation A similar patch test made with quinine water was negative probably because of the minute amount of quinine present

This patient showed an unusual reaction to the drinking of quinine water He was aware of his sensitivity to quinine and had avoided this preparation for years Assuming that he had six drinks of gin and tonic, he would have consumed about 24 oz of the quinine water It has been reported (Yohalen, S B Quinine in Tonic Water, Correspondence, *J A M A* 153 1304 [Dec 5] 1953) that some quinine water contains 30 mg of quinine per pint Therefore, it seems likely that our patient consumed about 45 mg of quinine during a three-hour period People who are sensitive to quinine may have severe reactions after the ingestion of a small amount of quinine as in this case Yohalen reported the case of a man who drank six to eight gin and tonics a day over a long period About seven weeks before consulting a physician he noticed severe tinnitus and a loss of hearing A tentative diagnosis of meningioma was made and surgery contemplated On a general examination before operation, the above history was obtained On ceasing to drink gin and tonic, the patient had a remission of all of his symptoms After this, a test dose of 150 mg of quinine produced a recurrence of his tinnitus and deafness It is well, therefore, to remember that tiny doses of quinine in a sensitive person may produce severe generalized reactions which can assume many different forms

CASHEW NUT DERMATITIS

To the Editor –Dermatitis from the cashew nut is extremely rare in the United States, since the tree grows chiefly in tropical America, Africa, and the West Indies We have observed a patient in whom contact with the rind on two occasions produced a dermatitis Dr J C White devoted a chapter of his book (Dermatitis Venenata, Boston, Cupples and Hurd, 1887, pp 71-72) to cashew nut dermatitis and stated that the tree bears an edible nut, but that its rind or mesocarp contains an oily fluid called cardol that turns black on exposure to the air and acts as a severe irritant to the skin Prior to shipment, the dried nuts are roasted, causing the outer shell to burst open and release the oil, which takes fire, giving off fumes which may irritate the eyes and skin

Our patient, a 60-year-old woman, gathered raw cashew nuts in the shell while traveling in Ceylon That evening a severe inflammatory dermatitis of the hands, with scattered areas of inflammation on the face and neck, developed At the time she did not realize the cause of her dermatitis, and with treatment it partially subsided On her return to the United States, she still had remnants of the eruption and much itching There was still clear evidence of a contact dermatitis, but, in spite of intensive questioning, there was no clue as to the cause Under treatment the skin cleared completely within five days Two weeks later, while cleaning out one of her bags, she found 12 nuts that she had brought home with her and opened them to show to her family At this time she noticed that a large amount of oil was released Within two hours a burning sensation of her hands, face, and neck developed, and by the following morning they were markedly inflamed and swollen She then realized that both attacks occurred within a few hours after handling cashew nuts, and, when she came in for treatment, she informed us that she suspected that this was the cause of her outbreaks In view of the extensive travels of United States citizens, others may incur a similar eruption, one that is scarcely mentioned in the textbooks

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Health and Accident Insurance Common Meaning of "Hernia"—This was an action to recover hospital and medical expenses, under a health and accident insurance policy, together with statutory penalties and attorney's fees. A judgment in the trial court for the plaintiff was reversed by the Court of Appeal, First Circuit, so the plaintiff appealed to the Supreme Court of Louisiana.

The policy in question provided for the payment of hospital and medical expenses in the event of illness or accident. While this policy was in full force and effect, the plaintiff developed a diaphragmatic hernia that consisted of the projection of the stomach into the thoracic cavity through the opening in the diaphragm normally occupied by the esophagus and that was large enough to permit the stomach freely to enter into the thoracic cavity. This necessitated an operation at considerable expense to the plaintiff. The defendant insurance company refused to pay the plaintiff's claim because of article 4 of the policy that provided twelve consecutive months of continuous membership under this certificate before LPS will assume liability for payment of surgical or medical services, or hospital care for preexisting conditions, tonsils, adenoids, hemorrhoids, and hernia.

The question, said the Supreme Court, is whether the word "hernia" as used in the exclusion clause was to be construed in accordance with article 1,947 or in accordance with article 1,946 of the Louisiana Civil Code. Article 1,947 provides that technical phrases are to be interpreted according to their received meaning with those who profess the art or profession to which they belong, while Article 1,946 provides that the words of a contract are to be construed in their common and usual signification. In a strict, technical and medical sense, the court continued, a hernia is any protrusion consisting of an organ or part projecting through some natural or accidental opening in the walls of its natural cavity. Inguinal, femoral, umbilical, epigastric, and diaphragmatic hernias are a few that are associated with the abdomen. In its technical sense, "hernia" also includes ruptured intervertebral disc, cerebral hernia, hernia of the eye, hernia of the lung, and, in fact, any protrusion through an abnormal opening. In its ordinary, popular sense, however, "hernia" means simply a rupture or noticeable protrusion from some part of the abdominal cavity. The layman's common conception of a hernia, in fact, is a protrusion through the front abdominal wall.

The courts of this state, in construing medical words and phrases in health, accident, and sickness policies, have consistently held that such words and phrases should be understood in their plain, ordinary, and popular sense rather than in their scientific sense. The Supreme Court said that it did not think the parties here intended that "hernia" should include, for example, a hernia of the brain or a hernia of the lung. The exclusion clause concluded the court, should therefore be construed in accordance with article 1,946, and "hernia" should be given its popular and ordinary meaning of a rupture or noticeable protrusion through the front abdominal wall.

The defendant further contended, however, that, since "hernia" in its customary usage is generally identified with hernias relating to the abdomen, one of which is diaphragmatic hernia, the exclusion clause in the policy still applies, but the court held that a diaphragmatic hernia is still not a hernia within what it had found to be the common and ordinary meaning of the word. Accordingly, the judgment of the Court of Appeal, First Circuit, was reversed and set aside, and the judgment of the trial court in favor of the plaintiff was made the judgment of the Supreme Court. *Seguin v Continental Service Life & Health Insurance Company, 89 So (2) 113 (La, 1956)*

Workmen's Compensation Acts Tuberculosis as Occupational Disease of Nurse—This was an action for an award under the Pennsylvania Occupational Disease Act. From an order granting such award, the defendant hospital appealed to the superior court of Pennsylvania.

During the time the plaintiff was a nurse assigned to the maternity, medical, and surgical wards of the Carbondale General Hospital, she developed pulmonary tuberculosis. The hospital did not knowingly admit tuberculous patients. Evidence was presented, however, to show that during her tenure at the hospital the plaintiff had been exposed to patients with tuberculosis who had been admitted to the various wards. The Pennsylvania Occupational Disease Act as amended July 19, 1951, added tuberculosis as an occupational disease in the following words, "Tuberculosis in the occupation of nursing in hospitals or sanitaria involving exposure to such disease." The plaintiff contended that she was covered by this provision. The defendant, on the other hand, contended that the plaintiff did not develop pulmonary tuberculosis as a result of her employment by the hospital.

The compensation board found that the plaintiff was exposed to and became infected with tuberculosis while in the employment of the defendant hospital. The Occupational Disease Act provides "If it be shown that the employee, at or immediately before the date of disability, was employed in any occupation or industry in which the occupational disease is a hazard, it shall be presumed that the employee's occupational disease arose out of and in the course of his employment, but the presumption shall not be conclusive The board further found that the defendant had failed to rebut this presumption

The Superior Court, on appeal, pointed out that there was medical evidence in the case indicating that the rate of transmission of tuberculosis, a communicable disease, in any hospital is very low, but that the incidence of acquiring tuberculosis among general hospital personnel is higher than that of the general population because such personnel come in contact with unrecognized pulmonary tuberculosis and fail to take the precautionary measures that hospital personnel in tuberculosis sanitorium take as a matter of routine Under the Pennsylvania Occupational Disease Act, the court continued, a presumption arose that the plaintiff's pulmonary tuberculosis developed out of and in the course of her employment, and that such presumption was not successfully rebutted The court also held that the Occupational Disease Act must be liberally construed in favor of the employee and that the evidence amply supported the board's findings Accordingly the award in favor of the plaintiff nurse was affirmed *Neary v Carbondale General Hospital, 124 A 2d 470 (Pa , 1956)*

THE LEISURE CORNER

THE PLEASURES OF SAILING

Talk to a devotee of sailing and you will quickly learn that he does not regard it as just a run-of-the-mill sport Along with fun and excitement, he will tell you, it brings a deep-rooted satisfaction that other sports do not supply While sailing is sometimes erroneously regarded as a pleasure suited only to the proportions of a wealthy man's purse, this pastime can be enjoyed by anyone who will take the time to learn about the technique of choosing, buying, and fitting out a sailboat

Many doctors who have undergone a grueling year of medical practice find that sailing a craft, particularly a small boat, renders a most enjoyable and gratifying type of recreation There is no doubt that, for many, the instinct and longing to set sail on water is ready for release, but for some there may be diffidence about embarking on a new nautical experience

The more one sails and the more one sees of water, the stronger does the urge become to call one's own small craft 'home' 'Sea fever' is an incurable disease, and it becomes difficult to tell the precise moment when the victim succumbs, for its infectiousness comes on gradually The symptoms of 'sea fever' are many and varied They will appear when the sun shines through the windows of your office, and you begin to entertain visions of sunlit waters and to conjure up a picture of slender masts, or just at the moment you may be writing a medical history, you will find yourself thinking about the new bobstay or whether the sails should be tanned Contrary to the doctor's instinct for establishing a cure, there occurs an untamed desire to release this wonderful, incurable disease known as "sea fever' for the benefit of mankind, a disease from which its victims show little desire to recover

No two sailboats are ever alike, although they may be constructed by the same builder and built according to the same specifications Sailing like the practice of medicine, teaches confidence and humility, initiative and philosophy It teaches the physician sailor to be courageous, to take infinite pains At one moment the wind and the sea call for courage, determination, and cool judgment, at another, during a period of relaxation when you are anchored in the harbor, comes a peace of mind far beyond the comprehension of landsmen

In selecting a boat, two important circumstances should be considered first, the locality in which you will be sailing, and second, the amount of money you want to spend For example, if you live along coastal waters, a boat should be chosen based on its ability to take the ground easily It should have a center board that can be pulled up when you are sailing in shallow water to reduce the vessel's draft However, if sailing will take place on the south coast, one can do much better with a keel boat On the other hand, if intentions are to make reasonably long cruises, a totally different type of craft is required, unlike the ones used in sheltered waters or in class racing By and large, the size of a sailing craft is determined by the provisions of the pocketbook

A most popular type of craft is the 5-ton to 7-ton cruiser with a small cabin Certain basic principles of design should be kept in mind First, most boats are about three times as long as they are wide, with the length of the ship measured on the load water line Second, the draft of the ship, unless it is a centerboard craft, will be about one-fifth of the load water line The displacement tonnage of a ship is defined in terms of the amount of water displaced, and this, consequently, is the actual weight A small-sized boat has light displacement, indicating a fast vessel that will sail well, however, the accommodations will be small One of the most important factors associated with the purchase of a boat is its shape No matter how much money is spent on a boat, one with a badly balanced hull may prove dangerous

An engine is not an absolute necessity Any small, well-designed hull with a reasonable sail area is readily handled in the most crowded anchorage While an engine is undoubtedly useful at times, a sound boat should not be turned down categorically because it lacks an engine It is always possible to install an engine at a later period, contrariwise after a boat is sailed for a year or so without an engine, the decision may be to keep her engineless

Before a boat is purchased, it is important that the craft be properly examined, since there are many pitfalls for the unwary Even if the prospective purchaser has some knowledge and experience, enlisting the services of a professional boat surveyor will often bring to light faults that a layman would overlook A surveyor will be able to tell whether a boat is in sound condition, and he is able to judge whether it has a freak shape or appears well balanced If the sails are rotting and the hull is only in fair shape, he will probably advise against buying the boat However, if the hull is in first-class shape, he may advise the purchase of new sails

Many beginning sailors believe that it is better to commence learning the art of sailing on a very small boat This is a fallacy, a small craft does not assure easy mastery, nor is it safer than a large one A very small boat—a 12-ft dinghy, for instance—is so quick in its response to the helm and so easily capsized that it often proves to be tricky for the beginner The ideal craft for the new sailor has about a 4-ton to 5 ton yacht measurement with a moderate sail area In such a craft, the beginner will have time to think, moreover, if he does get caught in a blow, the vessel will be large enough to insure safety

Finally, when the boat has been purchased, it would be well to postpone sailing until you learn more about the craft Learn where the lines (rope) lead, find the bilge pump and make certain it works, and examine the ballast to see just where it is placed and how much there is Examine the anchor and the cable Find the compass Is there a foghorn? If not, get one A boat hook? Navigation lights? Are all the sails present, and are there clean, strong sailbags?

Next there is the matter of learning the various parts and fittings of the craft and becoming acquainted with their functions A number of simple navigation rules should be followed in order to enable the new navigator to conduct the craft from one place to another with safety The Golden Rule in navigation is summed up in these words Always know your ship s position ' To follow this precept, three items are essential a compass, the chart of the area in which one is sailing, and a set of navigational instruments, including a pair of parallel rules, dividers, a sharp pencil, a station pointer, and a course-setting protractor Without these basic requirements it is foolhardy to sail The larger the compass, the more accurate it is Actually, steering a boat by compass is a simple matter

In the art of helmsmanship lies the deepest pleasure of sailing The man at the helm is the focal point in sailing It is he who can best "feel" the boat, sensing the slightest shifts of the wind right through his hands while watching a course, either by a mark on the shore, by compass, or by a star in the heavens

Doctors, who ordinarily spend little time with their families because of the pressure of their work, have found sailing an enjoyable means for welding family ties Children relish the idea of going sailing with their fathers and being able to participate in some of the associated pleasures such as fishing and swimming Sailing levels the ages of two generations, leads to wholesome friendships among adults, makes a knowledge of geography and map reading necessary, presents an opportunity for healthful exercise, and produces endless subjects for conversation

If a doctor cannot get enough of sailing during the warm-weather months, iceboating presents a seasonal variation for the more energetic members of the medical profession Nowhere has iceboating been followed more diligently and with such enthusiasm as in the United States and Canada The Great Lakes region offers thousands of miles of frozen water suitable for iceboating

At first, the sensation of iceboating is that of gliding through space, with a feeling associated with flying The mere notion of being conveyed through the air in a boat, at a rate equal to the speed of a fast train, will stir the younger contingent of the medical profession, if not the middle-aged People who have experienced the extraordinary velocity of an iceboat declare that, when the initial apprehension of participating in lightning-like speeds is overcome, fascination with the sport grows literally by leaps and bounds

MEDICAL FILM REVIEWS

Block Dissection and Pneumonectomy for Bronchogenic Carcinoma, Left Side 16 mm, color, silent, showing time 28 minutes Prepared by John F Higginson, M D, Portland Ore Produced in 1955 by and procurable on loan from Medical Illustration Service Veterans Administration Hospital, Portland, Ore

The author's technique in performing a radical pneumonectomy and mediastinal node dissection en bloc is demonstrated This technique includes dissection from the cupola of the chest to the diaphragm, including resection of the pericardium The purpose of the film is to demonstrate the radiographic findings and the surgical pathology of bronchogenic carcinoma The surgical technique is excellent The addition of a sound track to this film would be desirable Although it is well titled, the film needs additional comments and explanations during the demonstration of the surgical technique The photography is well done The film can be recommended to surgeons interested in this procedure

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Clinical and Anatomic Features in 500 Patients with Fatal Acute Myocardial Infarction K T Lee, W A Thomas, E R Rabin and others Circulation 15 197-202 (Feb) 1957 [New York]

Autopsy was performed on 500 patients who died during the period from 1910 to 1954 from acute myocardial infarction Of these, 429 (86%) died within 3 weeks after the onset of symptoms Only 50% gave a history of previous angina pectoris It appears, therefore, that fatal acute myocardial infarction may occur without previous warning Chest pain was the chief complaint of 64% of the 429 patients Anatomic evidence of previous myocardial infarction was present in 239 patients (47 9%) The clinical and anatomic aspects of these patients were similar to those in patients without previous myocardial infarction The correct diagnosis of this disease had not been made in 97 patients (19 4%) during life Complicating features such as major operations often obscured the clinical findings in these patients The only anatomic characteristic found to be different, as compared with those in patients whose conditions were diagnosed correctly during life, was the smaller size of the myocardial infarct Chest pain was much less common

Cretinism Maccarini H Prensa med argent 43 2805-2814 (Sept 14) 1956 (In Spanish) [Buenos Aires]

Endemic cretinism is due to congenital athyreosis It occurs frequently in goiterous regions and more frequently in men than in women The condition is marked by arrested physical and mental development, dwarfism, deformities of the bones and of the soft parts of the body, and disorders of the sense organs and of certain groups of glands The disease starts at birth with early symptoms of athyreosis The arrest of physical development becomes more evident with the increasing age of the patient A diagnosis is made by the following data (1) the typical dwarfish deformed, and idiotic aspect of the patient, (2) thick, dry, wrinkled skin, (3) lateness in learning to walk and talk, (4) chronic and persistent constipation, (5) a discrepancy between the real and apparent age of the patient, and (6) roentgenographic signs of retarded ossification of the epiphysis of the tarsus, wrist, and femoral head The treatment consists of administration of dried thyroid extract, which casuses great improvement of the physical and mental condition provided it is given early in the course of the disease The drug is given according to Mean's dosage schedule Two cases are reported In 1 patient the symptoms of athyreosis appeared when the infant was 7 days old The treatment with thyroid extract was immediately started and has been given to the patient throughout her life When last seen the patient was 12 years old Her height and weight were normal She had repeated the 1st and 2nd grades and was in the 3rd grade Her behavior was normal Her IQ was 90

The 2nd patient had sporadic cretinism She was seen for the first time at the age of 9 years and had typical symptoms of the condition Her height and weight correspond to those of a 3-year-old child Ossification of the epiphysis of the tarsus, wrists, and femoral head corresponded to that in a child of 1 year She is an idiot Treatment with thyroid extract was started According to the literature, the administration of thyroid extract late in the course of cretinism may cause a slight improvement in the physical development of the patient, but mental condition cannot be improved Iodide therapy given early in the course of cretinism may also cause some physical and mental improvement, but, when given late, the physical development may improve so that the patients are transformed from inoffensive idiots into troublesome ones

Myocardial Infarctions at the Queen's Hospital, January 1, 1950 to January 1, 1955 H C Gotshalk Hawaii M J 16 273-274 (Jan -Feb) 1957 [Honolulu]

Of 433 patients with myocardial infarction treated at Queen's Hospital (the largest private general hospital in the Territory of Hawaii) in a 5-year period, 131 (30%) died Of the 156 patients who received anticoagulant therapy in the form of heparin or dicumarol, 24 (15%) died, whereas, of the 277 who were treated only with bed rest, oxygen and other symptomatic measures, 122 or 44% died The author concludes that properly controlled and administered anticoagulant therapy produces better results than is achieved without these drugs

Medical Versus Surgical Management for the Complication of Hemorrhage in Duodenal Ulcer R S Boles Jr, W J Cassidy and S M Jordan Gastroenterology 32 52-59 (Jan) 1957 [Baltimore]

Of 266 patients with bleeding duodenal ulcer, 132 were treated for their 1st hemorrhage and 134 had a history of previous hemorrhage Of the 266 patients, 141 were treated medically and 125 were treated by subtotal gastrectomy Of the 141 patients who were

The place of publication of the periodicals appears in brackets preceding each abstract

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals Requests for periodicals should be addressed Library, American Medical Association Periodical files cover 1948 to date only and no photoduplication services are available No charge is made to members, but the fee for others is 15 cents in stamps for each item Only three periodicals may be borrowed at one time and they must not be kept longer than five days Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them followed up for an average period of about 4½ years, 38 (26 9%) had a subsequent hemorrhage Ninety-five of the 141 patients were treated for their first hemorrhage, and 26 (27 4%) of these had a subsequent hemorrhage Of 46 patients treated for a recurrent hemorrhage, 12 (26 1%) had a subsequent hemorrhage Of the 125 surgically treated patients who were followed up for an average period of 4 years, 19 (15 2%) had a subsequent hemorrhage Thirty-seven of the 125 patients were operated on for their first hemorrhage, and 4 (10 8%) of these had a subsequent hemorrhage Of 88 patients operated on for a recurrent hemorrhage, 15 (17%) had a subsequent hemorrhage

Thus, with both medical and surgical treatment, recurrent hemorrhage may be expected during the average follow-up periods of 4½ and 4 years The fact that the average follow-up time for the medically treated patients was a half year longer than for the surgically treated allowed more time for recurrent hemorrhage to occur in the medically treated patients The history of multiple versus single hemorrhage appeared to have no prognostic significance in the medically treated patients A somewhat higher percentage of subsequent hemorrhage was found among surgically treated patients in the multiple-hemorrhage than in the single-hemorrhage group of patients who bled after treatment, those who had had surgical treatment bled subsequently in a somewhat earlier period than did those who had had medical treatment The statistics of ulcer recurrence show that the duration of follow-up is in direct ratio to the number of recurrences In the average follow-up periods of about 4 years for both the surgically and medically treated groups, the recurrence rate of hemorrhage was disappointing to the patient and both disappointing and challenging to the physician

A Clinical Evaluation of Tubeless Gastric Analysis R J Bolt, T G Ossius and H M Pollard Gastroenterology 32 34-41 (Jan) 1957 [Baltimore]

Segal's azure A–cation exchange-resin test for the qualitative detection of free hydrochloric acid was carried out in 184 men and 9 women between the ages of 19 and 80 years Ninety of these 193 persons were also subjected to gastric intubation using 0 5 mg of histamine base parenterally as the stimulant and Topfer's reagent for the determination of free hydrochloric acid They, thus, were tested by both the tube and tubeless methods The tubeless test was carried out in 132 of the 193 persons in the course of a routine annual check-up and the remaining 61 were hospitalized The persons tested did not have breakfast They were given a capsule of 0 5 Gm of caffeine sodium benzoate in one-half glass of water and were asked to void 1 hour later and to save this urine in a bottle marked control A suspension of granules of an azure A–ion-exchange compound (containing about 45 mg of azure A per gram of carboxylic cation-exchange resin) in one-fourth glass of water was given, and 2 hours after taking it the person tested voided and saved the entire quantity of the urine in a bottle labelled 'urine sample

The 2-hour urine specimen, but not the control specimen, of 129 (67%) of the 193 persons tested was blue after both specimens had been diluted with water to 300 cc , denoting the presence of free hydrochloric acid in the stomach The blue color in the 2-hour urine specimen became apparent only after boiling in 42 (21%) of the persons tested Comparison with color standards after boiling was necessary with only 8 specimens (4 5%) in order to confirm the presence of free hydrochloric acid Of the 193 persons tested, 179 (93%) were, therefore, considered to have free hydrochloric acid in the stomach Unidentified pigments in 1 2-hour urine specimen prevented adequate color comparison In 13 (6 7%) specimens, no color or a blue color less intense than the 0 3-mg standard after boiling was shown, and this signified achlorhydria Eighty (89%) of the persons in whom the gastric secretory status had been determined by the standard gastric intubation procedure were shown to be acid secretors, and 76 (95%) of these showed evidence of free hydrochloric acid secretion on a single tubeless test Three (3 8%) of the 80 known acid secretors failed to show acid with a single tubeless test and there was color interference in the tubeless test in 1 Ten of the 90 persons were shown to have persistent achlorhydria by the histamine–gastric tube test The 2-hour urine specimens of the 10 persons remained lighter in color than the 0 3-mg standard, indicating achlorhydria

The azure A–cation-exchange-resin test for the presence of free hydrochloric acid is a simple test applicable to surveys of large groups of persons The reliability of the test in distinguishing those persons who do not secrete hydrochloric acid is supported by the authors' results and those reported in the literature The substance used in performing the test has so far proved to be relatively free of serious side-effects The use of the test in patients with severe renal disease gastric obstruction diarrhea and malabsorption syndromes requires further evaluation but the test will probably prove to be unreliable under such circumstances

Primary Aldosteronism Report of a Case and Discussion of the Pathogenesis D Fine, E Meiselas J Colsky and others New England J Med 256 147-152 (Jan 24) 1957 [Boston]

A 33-year-old patient was admitted to the Maimonides Hospital of Brooklyn N Y, in February, 1952 The finding of muscle weakness hypertension, hypokalemic alkalosis and hypernatremia, high urinary salt-retaining activity, and an adrenocortical adenoma with marked aldosterone-like activity led to the diagnosis of primary aldosteronism The symptomatology and the renal-metabolic defects were less intense in this patient than in previously reported cases The endocrine disorder was associated with symptoms of rheumatic heart disease The patient was admitted repeatedly to the hospital At his 13th and last admission in August, 1954, a final attempt was made to locate an adrenal mass by x-ray study before surgery The patient refused to permit further studies He died suddenly several days after his discharge from the hospital. Autopsy showed a tumor completely within the cortex of the left adrenal gland. Bioassay of an extract of the adrenal adenoma revealed a sodium-retaining activity of 111,000 equivalents of gamma desoxycorticosterone acetate (DOCA) per kilogram of tumor tissue. These observations suggest, that, as proposed for DOCA administration, the disturbances of primary aldosteronism derive in the first instance from accelerated tubular reabsorption of sodium that causes augmented excretion and negative balance of potassium. Surgical removal of hyperfunctioning adrenal tissue remains the only satisfactory treatment for primary aldosteronism.

SURGERY

The Treatment of Massive Hemorrhage from Gastric or Duodenal Ulcers. E. Ungeheuer. German M. Month 1:357-359 (Dec.) 1956 (In English) [Stuttgart, Germany].

Of 125 patients with peptic ulcer who were operated on because of massive gastric hemorrhage, 11 (8.8%) died. Of 51 patients who were operated on early, i. e., 24 hours after the onset of bleeding, 2 (3.9%) died. Of the remaining 74 patients, who were operated on late, i. e., from 3 to 10 days after the onset of bleeding, when conservative treatment had failed to prevent a second hemorrhage, 9 (12.1%) died. Although these results are weighted by the higher case fatality rate of the patients who were operated on late, they are better than those of purely medical treatment reported in the literature, with case fatality rates between 2.5 and 31%. A case fatality rate of 9% is to be considered as a clear sign of the superiority of surgical over conservative treatment.

Another advantage of surgical intervention is the permanency of the result obtained. Medical treatment does not banish the risk of recurrence of either the ulcer or the hemorrhage, nor does it eliminate the possibility of perforation or a malignant degeneration of a chronic ulcer. After a Billroth 2 operation, which is the method of choice in massive hemorrhage, these risks are permanently disposed of at once. Gastrectomy also is justified in patients with massive intestinal hemorrhage in whom laparotomy fails to reveal a palpable ulcer of the stomach or duodenum and in whom the possibility of bleeding from esophageal varices has been excluded by previous x-ray examination. Endotracheal anesthesia was preferred, and great importance was attached to a high oxygen concentration in the anesthetic mixture. The patient's blood pressure was never lowered artificially in order to prevent exposure of the anemic patients to the risks of further tissue hypoxia.

Considering that 80 to 90% of massive hemorrhages are from chronic ulcers and that these patients are particularly likely to have recurrent hemorrhages, with fatal results in 70 to 75%, it is clearly advisable to remedy this condition once and for all by early operation. This obviates the necessity of operating under unfavorable conditions on an exsanguinated patient when a few days earlier operation could have been performed without any great risk. To a young patient without a history of ulcer and with a mild hemorrhage that stops within a few hours, the customary medical treatment can be given just as competently by the surgeon, who will be ready to operate if the necessity arises. In practice, medical management alone is hardly ever sufficient. The widely divergent views about treatment should, therefore, be revised in the light of the favorable results of early operation.

Esophageal Diverticula. R. P. McBurney. South. M. J. 50:145-150 (Feb.) 1957 [Birmingham, Ala.].

While diverticula of the esophagus are not common, they are increasing in frequency with the increasing age of the population. Pulsion diverticula usually occur in the pharyngoesophageal area and less frequently in the epiphrenic area. They apparently are produced by pressure from the inside of the esophagus that causes herniation of the mucosa through the muscular walls. The sac of such a diverticulum is composed of mucosa, submucosa, and only vestiges of attentuated muscle. The traction diverticulum contains all the layers of the esophageal wall and is caused by inflammatory tissue pulling on the esophageal wall. Such diverticula usually are found in the midesophagus near the tracheobronchial lymph nodes. In the author's series of 57 patients, 32 had the pulsion type of pharyngoesophageal diverticula, 17 had a midthoracic traction type of diverticula, and 8 had a epiphrenic diverticulum. Most patients were in the 5th, 6th, and 7th decades of life.

Symptoms varied with the location of the diverticulum. In the pharyngoesophageal type the most common symptom was dysphagia. Weight loss, dehydration, regurgitation of food and liquid, a sense of fulness, or mass in the neck and substernal pain all were noted frequently. Repeated episodes of aspiration pneumonitis was a presenting complaint in 2 cases. Some patients complained of a gurgling noise in the neck, others that the pillow was wet with saliva and food when they awoke in the mornings. A few had coughing spells that awakened them at night. The midthoracic traction diverticula were, as a rule, asymptomatic. Five of the 17 patients with this type, however, complained of dysphagia. The patients with epiphrenic diverticulums complained mainly of epigastric and substernal distress, nausea and vomiting, dysphagia, and abdominal distention.

The x-ray examination is the keystone of correct diagnosis and is positive in nearly all cases. Esophagoscopy has been strongly advised in the past, but in recent years there has been a tendency to do fewer such examinations. The danger of perforation outweighs the value of the possible information obtained. Treatment was surgical in 18 patients; in the remaining 39, operation was either not advised or refused. Some of the patients in whom operation was not advised were seen in earlier years when it was thought that repair of esophageal diverticulum was dangerous. Many of these patients would now undoubtedly be advised to have surgical treatment. Of the resections for pharyngoesophageal diverticula 7 were 2 stage and 6 were 1 stage, and 2 patients had the 1st stage of a 2-

stage operation with gastrostomy The 2 resections for traction diverticula and the 1 for epiphrenic diverticulum were all 1-stage procedures The author prefers the 1-stage diverticulectomy

Management of Acute Empyema Thoracis P L Rai Punjab M J 6 171-184 (Nov) 1956 [Jullundur City, India]

Rai believes that empyema cannot be cured without evacuation of the pus The sulfonamides and penicillin prove useful in fighting the infection, but they must be combined with aspiration or surgical drainage The author discusses the indications for and the techniques, as well as the advantages and disadvantages, of the 3 methods used in the 96 patients with acute empyema treated by him between 1941 and 1955 Of these patients 12 discontinued treatment against medical advice Forty-two of the remaining 84 were treated by aspiration and chemotherapy, with the result that 29 were cured, the process became chronic in 3, and 10 died The closed method of intercostal drainage was used in 10 patients, 7 of these were cured, the empyema became chronic in 1, and the other 2 died An open operation with rib resection was performed on 32 patients, 25 were cured, the condition became chronic in 2, and 5 died

Severe Hemorrhages from the Esophagus, Stomach and Duodenum J Vandenbroucke Belg tijdschr geneesk 13 121-128 (Jan 15) 1957 (In Flemish) [Leuven, Belgium]

In a series of 137 patients with severe hemorrhages of the esophagus, stomach, and duodenum, the hemorrhage was due to gastric carcinoma in 9 patients, ulcer of the stomach in 14, duodenal ulcer in 48, and portal hypertension in 27 patients Sixteen of the 18 deaths occurred in these 98 patients The 9 deaths among the 23 patients with portal hypertension and cirrhosis occurred in patients ranging in age from 39 to 63 years at the time of death The 4 deaths among the 14 patients with severe hemorrhage from ulcers of the stomach occurred at from 51 to 61 years of age The deaths of the other 5 patients occurred at rather advanced ages Unusual causes of severe upper gastrointestinal hemorrhages were observed in 14 of the 137 patients These included a woman with a gastric polyp, a 28-year-old man with a pulmonoesophageal fistula, a 53-year-old man who had periarteritis nodosa and duodenal ulcer, 3 patients with carcinoma of the pancreas (whose severe hemorrhages were due to perforation into the stomach or duodenum, ulcer, or thrombosis of the splenic vein with portal hypertension respectively), a woman with angioma of the stomach, a patient with carcinoma of the gallbladder, 2 patients with hiatal hernia, and 3 patients with hemorrhagic gastritis

Hemorrhagic diathesis seems rarely to be responsible for severe hemorrhages of the upper gastrointestinal tract In 25 of the 137 patients (18%) the origin of the severe hemorrhages was not found In other statistical reports this percentage ranges from 10 to 25% The author emphasizes that early roentgenologic examination and gastroscopy will reduce this percentage These techniques will also reveal some of the rare causes of the severe hemorrhages, which, in many instances, will be amenable to surgical therapy In patients over 50 years of age who have severe bleeding from duodenal or gastric ulcers, medical treatment will not always be effective so immedicate surgical treatment will be necessary This was the case in 7 of 62 patients in this series A gastrectomy is usually advisable in severe hemorrhage from a postbulbar ulcer Transfusions may have to be given in generous amounts, but they are unnecessary when the hemoglobin level is above 65% and the systolic blood pressure above 100 mm Hg In patients with bleeding gastric or duodenal ulcers, the author prefers early and continued feeding to starvation A blind gastrectomy (without localization of the cause of bleeding) may be advisable Resection of the esophagus above the cardia with ligation of the varices was life-saving in 3 patients with threatening hemorrhages from esophageal varices caused by portal hypertension

Double Fractures of the Leg 25 Cases P Boutin Rev chir orthop 42 647-663 (No 5) 1956 (In French) [Paris]

The author reports on 5 recent cases of double fractures of 1 or both bones of the leg treated primarily and on 20 cases of double fractures of 1 or both bones of the leg that were given secondary treatment for poor reduction, pseudarthrosis, union with deformity, or osteitis Most of the 25 patients had suffered violent injuries by direct impact in parachuting or falling from a running train or from a scaffold or in the war One-third of the patients had associated fractures of the femur, the opposite leg, the upper extremities, or the cranium The double fracture of the leg presented itself as an upper oblique fracture in the upper third of the leg and as a lower transverse fracture at the point where the lower third of the leg begins and the median third of the leg ends, the 2 fracture areas being separated by a diaphysial intermediary fragment of 10 or 12 cm There was extensive detachment of the periostomuscular cylinder that ensheathes the intermediary fragment

Fractures of this type are rare, and their treatment is difficult because of a tendency to pseudarthrosis Details are given concerning only the 20 patients who had been treated elsewhere and were given secondary treatment by the author Seven of the 20 had received primary treatment by osteosynthesis, and 13 had been treated with a plaster cast after reduction of the fracture Pseudarthrosis had occurred in 11 patients in 13 fracture areas Osteitis had occurred in 10 patients and union with deformity in 13 Five patients had pseudarthritis, osteitis, and union with deformity simultaneously Amputation had to be performed in 2 of the 5 patients and will probably be unavoidable in a 3rd The author recommends that, in patients with closed doubled fractures consisting of oblique upper fracture and transverse lower fracture, nailing combined with screws be used for the upper fracture and a bone graft and screws for the lower fracture In patients with oblique upper and lower fracture, nailing combined with screws should be used for both

In patients with transverse upper and lower fractures, nailing should be combined with a long bone graft and screws used as a bridge if the intermediary fragment is short, a graft with screws should be applied to each of the double fractures if the intermediary fragment is to long to be bridged This method of treatment, whether used for a recent closed double fracture or for one with pseudarthrosis, always resulted in healing within the normally required time and with anatomic axes Walking could be resumed fairly early because large nails of femur type that penetrated through the prespinal surface of the tibia and fitted perfectly were used (drilling is indispensable)

Although a satisfactory correction of the general axis of the leg might be obtained with relative ease by immobilization in a plaster cast, it is difficult to obtain simultaneously a satisfactory osseous coaptation at the level of each of the double fractures—a result that is, however, of greatest importance for the prevention of pseudarthrosis Traction exerted by the quadriceps muscle on the short upper fragment makes reduction difficult It is, therefore, necessary to use osteosynthesis by bone graft and screws rather than a plaster cast in most closed doubled fractures It was used for the treatment of 3 of the 5 recent double fractures In patients with open double fractures, the surgical treatment of the external wound should be combined with reduction, followed by strict immobilization with the aid of a plaster cast Osteosynthesis should be considered only after reduction has failed

Reflections on 40 Patients with Cancer of the Ascending Colon Statistical Study J Seneque and C-L Chatelin J chir 73 5 21 (Jan) 1957 (In French) [Paris]

All but 6 of the 40 patients whose records are reviewed here were between 50 and 80 years of age Although the sex incidence of cancer of the ascending colon is usually about equal, this group included 26 women and 14 men While diarrhea, intestinal hemorrhage, and tumor of the colon are generally regarded as the characteristic triad of this type of cancer, the authors found that the symptoms in their patients were usually different Refractory diarrhea led to examination in only 3, and intestinal hemorrhage was present in only 1 of the 40 patients Tumor in the right flank was observed in 19 of the patients, in 9 of these it was no longer resectable, in 4 although the tumor was voluminous and fixed by adhesions it could be extirpated, and in 6 the tumor was still mobile, being the size of an orange in 2 but small and difficult to detect in the other 4 Pain was present in all but 1 of the 40 patients Roentgenologic examination, although important in the diagnosis of tumor of the ascending colon, is not widely used

The cancer of the ascending colon was revealed in 28 of the 40 patients by acute or chronic obstruction, in 6 patients by perceptible tumor, and in 5 by peritoneal inflammation, in 1 patient the tumor was silent A 1-stage hemicolectomy was performed in 27 of the 40 patients, a 2-stage hemicolectomy in 4, palliative operations in 8, and an exploratory laparotomy in 1 There were 3 surgical deaths 1 after the exploratory laparotomy, 1 after a palliative operation, and 1 among the 27 patients undergoing a 1-stage hemicolectomy Seven of the 26 who survived the 1-stage hemicolectomy could not be followed up, and 8 of the remaining 19 have died In 6 of the 8 who died, the lymph nodes had become invaded, indicating that lymph node involvement signifies an unfavorable prognosis Eleven of the 19 were still living In the 7 who survived the palliative operations, the survival period at the time of writing had been relatively short, only 1 being alive after 10 months Of the 4 who underwent hemicolectomy in 2 stages, 3 have died

NEUROLOGY & PSYCHIATRY

Epidemiology of Nonbacterial Meningitis (Serous Viral Meningitis) in the Governmental District of Dusseldorf, Northern Rhine–Westphalia, 1956 C L P Traub and J Posch Medizinische, no 4, pp 139-143 (Jan 26) 1957 (In German) [Stuttgart, Germany]

An epidemic of nonbacterial meningitis in the form of serous viral meningitis of partly pandemic type occurred in the district of Dusseldorf, Germany, between June and September, 1956 The district consists of 14 urban and 9 rural subdistricts and has a population of about 5 million The total number of cases of abacterial meningitis was estimated to be 45,000 Statistical data concerning the age and sex of 451 patients were available Of these, 305 (67 75%) were infants or children and 146 (32 25%) were over 16 years of age Boys predominated in a ratio of 2 1 among the 305 children Women predominated among the adults The age of 73% of the adults was 30 years or less Vomiting, severe frontal and supraorbital headache, mild meningeal irritation or mild stiffness of the neck, and a temporary rash similar to that of rubella on the face and thorax were the main symptoms An initial 2-day phase with temperature elevations to 104 F (40 C) was followed, after an afebrile interval of from 5 to 8 days, by a second period of fever of from 1 day's to 4 days' duration The meningitic symptoms predominated in this second period but subsided rapidly after lumbar puncture, which was performed mainly for diagnostic reasons The spinal fluid was fairly clear, but from 2,400 to 5,000, predominantly mononuclear, leukocytes per cubic millimeter were present The total protein level varied from 40 to 60 mg per 100 cc, and the reaction to Pandy's globulin test was weakly positive Complications did not occur, and there were no deaths The incubation period varied from 5 to 7 days

A previously unknown virus was isolated from the feces, sputum, and spinal fluid of the patients Complement-fixation tests for poliomyelitis, mumps, lymphocytic choriomeningitis, and influenza A virus in the blood and in the cerebrospinal fluid were negative The patients were given a proprietary, combined preparation of streptomycin and penicillin (Supracilline) and tetracycline to prevent secondary infections One hundred seventy-five cases of poliomyelitis were reported in the district of Dusseldorf in the same

ACC. 1538

period Epidemiologic connections between the serous viral meningitis and the poliomyelitis could be neither definitely established nor excluded

Epidemic Occurrence of Nonbacterial Benign Meningitis G Hennemann Medizinische no 4, pp 143-146 (Jan 26) 1957 (In German) [Stuttgart Germany]

An epidemic of nonbacterial meningitis occurred in Mainz and in several other cities and villages in the neighborhood of Mainz between July and October, 1956 The author reports on 37 men (58%) and 28 women (42%) between the ages of 14 and 50 years with nonbacterial meningitis The predominance of men might be explained by the fact that the men, because of their occupational activities, had more contact with the pathogenic agent than the women Most of the men were between the ages of 20 and 30 years, but there was still a high incidence of the disease among women between the ages of 30 and 40 The disease was characterized by a sudden onset, with fever, severe frontal headache, pain in the neck, recurrent vomiting, feeling of pressure in the orbits, severe back pain, and sweating Stiffness of the neck was observed in 90% of the patients and was most pronounced in the first 4 to 6 days of the disease The temperature varied from 100 4 F (38 C) to 102 2 F (39 C) The sedimentation rate was increased in two-thirds of the patients The leukocyte count was between 5,000 and 10,000 per cubic millimeter Definite leukopenia was rarely observed A mild lymphomonocytosis was found in about 40% of the patients The spinal fluid pressure was increased in most of the patients and in some above 300 mm H_2O The spinal fluid was clear in some patients and turbid in others, depending on its cell content Pleocytosis was pronounced The number of cells varied from 500 to 24,000 per cubic millimeter Mononuclear cells predominated in 60% of the patients Polynucleosis was observed in the early phase of the disease in one-third of the patients, but it became lymphocytosis in the course of the disease The increase in the total protein content of the spinal fluid was less pronounced and was below 3 Kaffka units in most patients The sugar content was not increased The patients were given antibiotics, sulfonamides, and cortisone, without notable effect Temperature was restored to normal by lysis or crisis after from 5 to 10 days The general condition and the meningeal irritation improved simultaneously A second rise of temperature with worsening of the findings in the spinal fluid for about 2 days was observed occasionally, but more than half of the patients were free of complaints after 2 weeks The patients were discharged from the hospital after 3 or 4 weeks, and at this time the number of cells in the spinal fluid was below 50 per cubic millimeter in 75% of the patients and not more than a 100 per cubic millimeter in the rest Complications were not observed The causative virus was not identified Differential diagnosis between nonbacterial meningitis and poliomyelitis was difficult in the initial stage of the disease and became possible only when the pronounced increase in cells in the spinal fluid was found not to be associated with paralysis

PEDIATRICS

Typhoid in Pregnancy as Cause of Neuropsychiatric Disorders in Infants Three Cases M Schachter Rev españ pediat 12 665 670 (Sept -Oct) 1956 (In Spanish) [Zaragoza, Spain]

Typhoid in the course of pregnancy may be the cause of neuropsychiatric disorders in the infants Three cases are reported in children of 5, 5, and 3 years of age In the 1st case, the mother had typhoid during the 1st month of pregnancy The child was born at full term When the child was observed at the age of 5 years, she showed deformities of the ears, anisodactylism and isodactylism, and signs of an operation for correction of palatine fissure and harelip She was mentally retarded and had severe behavior disorders The other 2 mothers had typhoid fever when they were in the 5th month of pregnancy Both children had convulsions One of them had symptoms suggestive of whooping cough for 9 months Both children had severe behavior disorders

The Follow-up Study of Hemangiomas of the Skin Treated and Untreated W Falk and D Levy A M A J Dis Child 93 165-172 (Feb) 1957 [Chicago]

Of 23 boys and 37 girls between the ages of 1 month and 4½ years with the strawberry type of vascular nevus of the skin, 52 had a single nevus each, 5 had 2 nevi, 2 had 3 nevi, and 1 had 4 nevi, a total of 72 lesions Fourteen of the 72 lesions were treated with radium because erosions and ulceration with hemorrhage or severe disfigurement of the body part were likely to occur The other 58 were left untreated The 60 patients were reexamined after a lapse of from 5 to 8 years Whenever the lesion was left to follow its natural course, it resolved without any residual scarring, 54 of 58 nevi had disappeared Most vascular nevi fare best when left to their natural course No active therapy should be undertaken except for nevi that are cosmetic blemishes or that cause functional impairment The question of therapy of the latter 2 types of lesions depends on the position and the size of the hemangioma and the general health of the child In most of these nevi early irradiation is to be advised and carried out to prevent ulceration and more severe functional impairment later in life

Three Cases of Eosinophilic Granuloma of the Pelvis in Children L Nitter Acta Radiol 46 731-738 (Dec) 1956 (In English) [Stockholm]

Reviewing earlier reports on eosinophilic granuloma, Nitter points out that, while Lichtenstein and Jaffe believed that eosinophilic granuloma is a disease *sui generis*, most authors now consider that the condition is related to Letterer-Siwe's disease and Hand-Schuller-Christian disease, all being different stages of the same disorder of the reticuloendothelial system Cases have been reported demonstrating transition from eosinophilic granuloma to Hand-Schuller-Christian disease The disease occurs more frequently in girls than in boys, 2 of the 3 patients reported here were girls aged 2½ and 2 years, respectively, and the other was an 18-month-old boy In all 3, the lesion was situated primarily in the pelvis, and in 2 of them it remained solitary The roentgenographic findings were typical in all of them The treatment was difficult by reason of the location One of the 2 girls and the boy were treated only with roentgen irradiation, after the histological diagnosis had been made, in 1 case by biopsy and in the other from tissue removed by scraping

In the third case surgical removal of the affected tissue was performed, but marked progression necessitated roentgenotherapy 6 months later Surgery has been employed to prevent irradiation damage to the ovaries In the first girl, there were several reasons for administering roentgenotherapy, and an attempt was made to avoid irradiation of the ovary as far as possible by using a small field and directing the beam tangentially In this girl and in the boy roentgenotherapy gave good results with rapid healing No new lesions were detected after 4 and 3 years, respectively No inhibition of longitudinal growth was observed in these 2 patients The radical operation performed in the third patient may possibly have contributed to the dissemination of the disease Subsequent roentgenotherapy had a favorable effect in this patient Further observation is needed to ascertain whether this is simply a case of multiple lesions or whether there will be transition to another phase of the disease The sedimentation rate was still high This and the newly detected localizations indicate that the disease was still active

Research on the Myelograms of Full-Term, Premature, and Postmature Babies During the First 10 Days of Life P Nicola Minerva pediat 8 1454-1468 (Nov 24) 1956 (In Italian) [Turin, Italy]

The myelogram of 5 full-term, 5 premature, and 5 postmature babies was studied on the 1st and on the 10th day after delivery The babies of the 1st group weighed from 3,050 to 3,750 Gm , their condition remained good throughout the period of observation, and they were all breast fed The babies of the 2nd group were born after from 29 to 32 weeks of gestation Their weight was from 1,200 to 1,800 Gm , and their conditions were good The babies of the 3rd group were born after from 42 to 44 weeks of gestation Their weight was 2,500 to 3,350 Gm , and 4 showed signs of asphyxia at birth They were all breast fed, and their conditions remained satisfactory although they showed symptoms caused by the prolonged pregnancy The myelograms of the full-term babies were characterized by an intense erythropoiesis manifested by a high erythroblastic content The examination made on the 10th day showed that the erythropoiesis had diminished markedly and the granuloblastic activity had increased The findings in the premature babies were similar to those in the full-term babies The erythropoiesis of the postmature infants was more intense than that of the other 2 groups Examination after the 10th day showed that the functional inhibition present in the other 2 groups was not so marked

The Day and Night Output of Urine in Enuresis D Vulliamy Arch Dis Childhood 31 439-443 (Dec) 1956 [London]

The day and night urinary output and the ratio of day to night volumes was determined in 22 children with enuresis and in 24 who did not have enuresis Conditions of diet and fluid intake were standardized in both groups Fluid intake apart from that in the food was 900 cc for children between the ages of 4 and 5 years, 1,050 cc in those between the ages of 6 and 8, and 1,200 cc in those between the ages of 9 and 12 Regulation of fluid intake and diet was begun 2 days before the collection of urine was started, and this continued over an average period of 5 days and nights for each child The sodium and potassium output was also measured, because it was hoped that this would assist in elucidating the cause of the anticipated nocturnal polyuria Most children passed between 150 and 400 cc of urine at night, the volume varying to some extent with age There was no significant difference between the volume passed at night by the children with enuresis and that by the controls There were, however, 4 children who passed amounts outside these limits and who may be said to have had nocturnal polyuria Two had enuresis, and 2 were controls No significant difference between the diurnal output of urine was observed in the children with enuresis and the controls The average day to night ratio of urinary output for the group with enuresis was 1 93, while that of the control group was 1 90 The figures for sodium and potassium did not add any useful information Thus, the theory that nocturnal polyuria is a common contributory cause of enuresis was not confirmed The association of relative nocturnal polyuria with steatorrhea was noted, but enuresis did not always accompany it The tendency for most children with enuresis to have a relatively small bladder capacity, as judged by the maximum volume passed in one act of micturition, was confirmed

Xanthomatosis Due to Stenosis of the Intrahepatic Bile Passages A Clinical Contribution O Lanciano and L Campea Pediat internaz 6 337-359 (Oct -Dec) 1956 (In Italian) [Rome]

A 7-year-old child with jaundice since his 8th day of life and xanthomatosis since he was 2 years and 7 months of age was first admitted to hospital when he was 1½ months old Hypocholic feces, bile pigments of the urine, and normal cholesterinemia were observed A tentative diagnosis of congenital partial obstruction of the bile passages was made At the age of 2½ years the child was subjected to an exploratory laparotomy The extrahepatic bile ducts were found normal, and a hepatic lymph node showed hyperplasia of the reticular cells After the operation, however, jaundice was still present The child was hospitalized again at the age of 7 years at which time somatic hypoplasia, marked jaundice, diffused cutaneous xanthomatosis, and marked hepatosplenomegaly were observed Laboratory tests showed the presence of stercobilin in the feces, of bile pigments and urobilin in the urine, and of a high bilirubin level in the serum The serum level of total lipids was 3,284 mg, total cholesterol 1,047 mg, and phospholipids 1,725 mg per 100 cc Roentgenologic examination showed diffused osteoporosis of the skeleton, the bile passages were not visualized The histological and chemical examination of a xanthomatous node showed the accumulation of intracellular and extracellular lipids and especially of cholesterol The case was diagnosed as xanthomatosis due to chronic partial obstruction of the bile ducts High lipemia is a characteristic sign of this disease

DERMATOLOGY

Malherbe's Mummified Tumor A G Martins Arq pat 28 123-204 (Dec) 1956 (In Portuguese) [Lisbon]

A series of 227 mummified epidermoid cysts (Malherbe's mummified tumors) in 205 patients was observed The disease is rare It is twice as frequent in women as in men The cysts seem to have their origin from embryonic ectodermal rests They consist of primary basal cells with tumor-growing capacity in certain regions of the skin The tumors grow slowly and spontaneously undergo degeneration with mummification, frequently followed by calcification and ossification

The tumors are benign, although in rare cases the histopathological picture may suggest malignancy The tumors do not metastasize, do not regress spontaneously, and do not recur after complete removal, but they may recur after an inadequate removal The tumor is not caused by syphilis, tuberculosis, or trauma, but there may be a familial history of frequency of tumors of various types The tumors occur, in order of frequency, on the face, scalp, neck, and arms They rarely appear on the trunk, chest, and legs They may be solitary or multiple, painless or painful, and some may itch The treatment consists of wide surgical removal Electrodieresis and postoperative roentgenotherapy are unnecessary unless the histopathological examination of the removed tissue shows mitosis or atypical cells Slow-growing solitary or multiple tumors need not be removed, but the patient should be examined at least once a year for the possibility of changes in the tumor Yearly observation is also necessary after removal of the tumors

UROLOGY

Complications of Nephrolithotomy with Special Reference to Secondary Hemorrhage W P Jordan and G C Tomskey J Urol 77 19-23 (Jan) 1957 [Baltimore]

The impetus for this study of the complications of nephrolithotomy was the occurrence of intractable hemorrhage in 2 patients within a short period of time The complications discussed occurred in the course of 75 operations The 2 cases of atelectasis and the 4 cases of thrombophlebitis might have followed any kind of major operation discussed The complications referable to the renal operations in these 75 patients were as follows secondary hemorrhage occurred in 7 It was controlled by conservative measures in 2, but nephrectomy was required in the other 5 Persistent urinary fistula occurred in 6, all of which were instances of severe infection in which drainage by nephrostomy had been necessary for long periods The fistula closed spontaneously in 5 patients, but the remaining patient required nephrectomy for a persistent renocutaneous fistula Perinephric abscess occurred in 2 patients In 1 of them in whom the infecting organism was of the genus Proteus, surgical drainage was sufficient but in the other in whom Micrococcus (Staphylococcus) pyogenes, var aureus was the causative organism, nephrectomy was necessary Recurrent calculus formation was a delayed complication in 7 patients, and in 4 of these nephrectomy became necessary In 2 other patients the kidney failed to function after nephrolithotomy

Thus complications due to nephrolithotomy numbered 24 or nearly 33% This is a high incidence for an operation that is performed to preserve function Secondary hemorrhage is presumably the result of necrosis and infarction of the renal parenchyma which are probably attributable, in many cases, to the use of mattress sutures for closure of the parenchymal wound A technique of closure is described in which these risks are eliminated In this technique the calyx is first closed with interrupted sutures of 000 absorbable surgical sutures All large vessels are tied separately The wound in the cortex is then approximated by interrupted double sutures of 0 chromic absorbable surgical sutures, tied over pieces of fat and muscle on each side of the wound A large, curved, cutting needle or a straight Keith needle can be used, but the preference of these authors is for the crochet type of needle designed by Dee, the use of which greatly simplifies closure Neither strangulation nor constriction of renal tissue has been observed in any of the 15 patients in whom this technique was used in the past year, and hemostasis has been satisfactory Because of its serious consequences, nephrolithotomy should not be performed unless there are definite contraindications to management by pyelolithotomy

Renal Hemangioma with Hematuria F Bierring Ugeskr læger 118 1459-1461 (Dec 6) 1956 (In Danish) [Copenhagen]

Renal hemangiomas are infrequent and present no characteristic roentgenologic changes Deformed calices and pelvis can be expected only in the case of larger hemangiomas and have been observed in but few patients Hematuria occurs when renal hemangiomas cause arrosion of the epithelium of the urinary duct, it is often intermittent and may be monosymptomatic or accompanied by colicky pain due to passage of a clot Cystoscopy shows the unilateral nature of the hematuria Most of the cases reported were discovered only after nephrectomy on diagnosis of essential hematuria Macroscopic unilateral hematuria without other cause and with or without few pyelographic changes should suggest possible renal hemangioma, especially if the symptom is of long duration This remote possibility does not justify an expectant attitude toward so grave a symptom as hematuria The patient reported on by Bierring had severe hematuria due to a small hemangioma, hematuria had occurred twice before the first time 19 years earlier The possibility of benign renal tumor was considered preoperatively Nephrectomy was performed Renal resection has been performed on only a few patients in whom the hemangioma was easily recognizable

The Meaning of Symptoms in the Diagnosis and Prognosis of Renal Tumors S Petkovic Urologia 23 113-124 (April 20) 1956 (In French) [Treviso, Italy]

A series of 100 patients with tumor in the parenchyma of the kidney were observed Of these 83 were subjected to nephrectomy, and 10 died A study of the meaning of the symptoms in these patients showed that both benign and malignant forms of tumor during the preoperative period may produce similar symptoms In malignant tumors, the triad of symptoms (hematuria pain, and edema), observed in 39 patients may indicate that the diagnosis has been made too late In benign tumors, those same symptoms did not prevent fairly good results Practically, however, these 3 symptoms mean that half the number of patients should be considered as lost Hematuria was the first symptom in 50 patients An attempt to base preoperative prognostic conclusions on this symptom give contrasting results The prognosis was either very good or very bad in patients who had hematuria for only a short time

The brief preoperative development of symptoms did not prevent death in some patients, but in others with a less malignant form of tumor the postoperative course was very smooth Sixty-two patients had sharp pain, 32 had colic, and 25 had no pain Persistent pain was a symptom of a high grade of malignancy, with probable metastasis Edema, present in 72 patients, is a bad prognostic sign if it is the initial symptom Absence of the 3 classic symptoms did not increase hope for better results Renal tumors with a long preoperative course with hematuria as a first sign are associated with a better prognosis than those in which edema is the first sign Loss of strength and of weight are bad prognostic signs The author believes that in most patients an accurate prognosis cannot be based on the histological examination Some with similar histological findings had very different prognoses A more accurate diagnosis can be based on the study of the anatomic stage of development of the tumor The author is pessimistic about the validity of the clinical signs as a means for an early diagnosis A pyelogram is conclusive only when the disease is already far advanced

Study of 229 Consecutive Cases of Total Perineal Prostatectomy for Cancer of the Prostate R D Turner and E Belt J Urol 77 62-77 (Jan) 1957 [Baltimore]

This paper analyzes 274 consecutive total perineal prostatectomies performed for suspected malignancy of the prostate gland The analyses were made with the help of punch cards, sorters, and tabulators for comparative study Forty-five cases were excluded because microscopic studies did not reveal malignant tissues the pathological reports were missing, or the primary cancer was in another organ Jewett's evaluation of the results of radical perineal prostatectomy for cancer of the prostate established the soundness and value of this operation The modified technique employed in the 229 cases analyzed here differs from Young's original operation in several ways 1 The approach through the perineum is between the rectum and the anal sphincters 2 No bladder cuff is routinely removed unless there is invasion into the bladder neck 3 Prior to 1946, a small portion (less than 1 cm) of the apex of the prostate was left in, in an effort to avoid injury to the external sphincter and to prevent incontinence Since 1946, the entire prostate, seminal vesicles, ampullae, and several centimeters of the vas deferens have been removed 4 The bladder neck is anastomosed directly to the urethra around a Foley catheter by 4 quadrant sutures

As regards morbidity, mortality, course, and complications, the 229 cases analyzed here closely resemble those presented by Jewett The central fact that emerged from his studies and from this one was that, in patients in whom cancer of the prostate is recognized early and in whom the prostate with its cancer is removed before the cancer has extended beyond the prostatic capsule, a 10-year survival rate is attained, which closely approximates the survival rate of patients of this same age group in the general population It follows that earlier recognition is of vital importance Simple digital examination of the posterior aspect of the prostate in the course of an ordinary rectal examination is a more effective means of discovering the presence of early cancer of the prostate than are more elaborate methods of study Hence, rectal examinations should be routinely made in men of the age group in which cancer of the prostate may be expected to occur An effective surgical procedure, total perineal prostatectomy, is available for cure of such cancers Total removal by urologists should be encouraged on the basis of the higher survival rate associated with this form of surgical attack

Non-Contrast-Producing Urinary Concretions as Cause of Obscure Symptoms and of Severe Renal Damage G Rodeck Chirurg 28 9-14 (Jan) 1957 (In German) [Berlin]

Most urinary calculi are revealed by roentgenographic methods, but a certain percentage do not produce shadows Such calculi may be the cause of hematuria, chronic infections of the urinary tract, damage to the renal parenchyma, and of colicky or continuous pains The author gives particular attention to the non-contrast-producing calculi of the ureters and of the renal pelvis, pointing out that those of the bladder are more readily recognized if not by cystoscopy by the use of a contrast medium The ray absorption factor determined by the chemical composition of the stone is not the only reason a concrement fails to produce a shadow Other factors are surrounding fluids, bones, vessels, and intestinal shadows To avoid diagnostic errors in the presence of non-contrast-producing calculi, it should be remembered that the presence of urinary calculi is always accompanied by signs of inflammation, which, if not due to bacterial infection, may be caused by mechanical irritation While ureteral calculi may cause signs of stasis, those lodged in the renal pelvis generally do not unless inflammatory symptoms have been intensified by bacterial infection producing excretory blockage, with dilatation of the renal calices If the lesion has advanced to this point it may be too late to save valuable tissue The most valuable aid in diagnosis is excretory urography and repeated retrograde and graduated contrast fillings with pyelography

In 1 of the author's patients the presence of a large stone that had become a mold of the renal pelvis on the left side and a ureteral stone on the right side was deduced from roentgenologic signs The large stone of the renal pelvis had remained unrecognized for years and during this time had produced severe tissular damage The development of the ureteral calculus on the right side produced a threatening situation, but, since no bacterial infection had supervened, a conserving operation could be planned for the left side The ureterotomy on the right side was well tolerated, and the postoperative excretory pyelography showed normal excretion with retrogression of the stasis Six weeks later a large coral-shaped uric acid calculus that had become a mold of the left renal pelvis was removed Although there was much cortical scarring, an organ-sparing operation was performed because of the bilateral nephrolithiasis Three points are stressed on the basis of this case history 1 The presence of a calculus cannot be excluded without contrast filling of the renal calices 2 The opposite kidney should always be examined, if an operation is planned on the kidney or ureter of one side 3 An organ-sparing operation may be successful even in the presence of large stones that have become a mold of the renal pelvis Such an operation should always be attempted if the lithiasis is bilateral The other 2 patients whose histories are presented had similar calculi of the renal pelvis Of 225 operations performed for urinary calculi, 51 were nephrectomies, 7 nephrotomies, 55 pyelotomies, 72 ureterotomies, and 40 suprapubic cystotomies There were 2 deaths, 1 from bronchopneumonia and 1 from urosepsis All the other patients were free from fistulas and had good excretory function at the time of discharge from the hospital

THERAPEUTICS

Cardiac Manifestations of Hypopotassemia in Patients Treated with Chlorpromazine R M Perrot, G Moreau-Gaudry and Y Le Borgne Presse med 64 2076 (Dec 12) 1956 (In French) [Paris]

The authors report on a 26-year-old man with a schizophrenic syndrome and a 56-year-old man with manic-depressive psychosis of the hypomanic type who were treated with chlorpromazine An arrhythmia with frequent extrasystoles appeared after 4 weeks of treatment with chlorpromazine in the younger patient The electrocardiogram showed a lowering of the ST segment and an inversion of the T wave These observations suggested hypopotassemia, which was confirmed by the laboratory finding of a blood potassium level of 130 mg per 100 cc (3 3 mEq per liter) The patient was given a daily dose of 2 Gm of potassium chloride orally The extrasystoles became less frequent, and, after 4 months of treatment with potassium chloride, the electrocardiogram was completely normal The older patient had a history of rheumatic fever Tachycardia was present when treatment with chlorpromazine was instituted, but severe arrhythmia with extrasystoles occurred after 4 months of treatment with chlorpromazine The patient was given 1 5 Gm of potassium chloride daily by mouth There was rapid clinical improvement, and the electrocardiogram became normal within 2 months Hypopotassemia, a relatively rare finding, had been reported previously in the course of artificial hibernation, chlorpromazine being one of the ingredients of the "lytic cocktail The authors emphasize the fact that the cardiac disturbances and the electrocardiographic changes in the two patients reported on disappeared after the administration of potassium chloride

Results of Treatment with a New Vasodilator in Patients with Severe Disturbances of Blood Supply in the Lower Extremities K Weghaupt Wien klin Wchnschr 69 31-32 (Jan 11) 1957 (In German) [Vienna]

Duvadilan, a proprietary preparation of 1-(*p*-hydroxyphenyl)-2-(1-methyl-2-phenoxyethylamino) propanol, which greatly increases the peripheral circulation in the extremities without causing a lowering of blood pressure or a significant increase of the pulse rate, was given to a 59-year-old woman with a malignant tumor of the vulva in whom a severe disturbance of circulation in the left lower extremity had occurred after combined surgical, x-ray, and radium treatment The patient had severe pain in the left lower extremity, the lateral portion of which showed a white discoloration The pulse in the left femoral artery was not palpable There was beginning gangrene, and paravertebral anesthesia of the sympathetic nerve with 10 cc of a 1% solution of procaine hydrochloride in the area of the 2nd and 3rd lumbar ganglions was ineffective Administration of large doses of other vasodilators such as nicotinic acid derivatives and *hydrogynated ergotoxic alkaloids also* failed Amputation was recommended by 4 surgeons but was refused by the patient

The entire lateral portion of the skin showed a blue-brown discoloration on the 22nd day after the onset of the first symptoms The entire foot showed the same discoloration, and the leg was cold and extremely painful Moist gangrene of 2 toes developed, and a burrowing ulcer occurred in the lateral portion of the leg Two ampuls of 10 mg of Duvadilan each were injected 3 times daily Pain in the extremity subsided, and a notably regressive tendency of the discoloration of the skin was observed within a few days after the institution of the treatment The necrotic portions of the skin sloughed off several days later, and the pulse of the femoral artery became faintly palpable Granulations in the area of the cutaneous defect caused healing of the ulcer The patient was discharged after 1 month of treatment with Duvadilan but continued treatment by taking 6 tablets of 10 mg of the drug orally daily for 2 months The drug was well tolerated Seven months after the institution of treatment the patient was able to walk long distances without discomfort, trophic disturbances were completely healed and the pulse of the femoral artery was readily palpable

Four additional patients with severe intermittent claudication due to arteriosclerosis were treated with Duvadilan The drug was given orally in daily doses of 60 mg The patients soon were able to walk longer distances before symptoms reappeared and finally were able to walk long distances without pain One of the patients had severe sciatic pain possibly caused by a disorder of nutrition of the nerve This pain subsided completely as a result of the treatment Duvadilan is considered a valuable drug, and its administration may make amputation unnecessary

Urinary Infections Due to 4, 4'-Diaminodiphenyl Sulphone Therapy Report of Three Cases F C Combes and M Reisch Brit J Dermat 69 25 27 (Jan) 1957 [London]

Diaminodiphenyl sulfone (dapsone) has been used effectively not only in tuberculosis and leprosy but also in many toxic bullous eruptions, especially dermatitis herpetiformis and pemphigus Urinary infections developed in 3 patients who were treated with dapsone for dermatitis herpetiformis, pemphigus vulgaris, and leprosy respectively When the administration of the drug was discontinued and a suitable antibiotic was given the patients recovered To ascertain why the prolonged administration of dapsone results in pyelonephritis rather than in intestinal disturbances that sometimes accompany the protracted administration of antibiotics, the absorption and excretion of the drug were studied After the administration of therapeutic doses of dapsone, it is found in all tissues and body fluids, the liver and kidney containing relatively high concentrations Minor disturbances such as repeated attacks of erythema nodosum, arthralgia, and peripheral neuritis due to intolerance of sulfone therapy are common, but side-reactions involving the urinary tract, such as reported here are not common The authors recommend that patients with slight albuminuria be given lower than ordinary dosages of dapsone When administering dapsone by mouth, it should be remembered that it is capable of provoking urinary infection by organisms resistant to it

Infections Complicating Cortisone Therapy F P Smith and E A Cleve New England J Med 256 104-108 (Jan 17) 1957 [Boston]

Six patients are reported in whom infection complicated cortisone therapy, 3 of them died The steroid had been given to 3 of the patients for rheumatoid arthritis, to 1 for rheumatic fever, and to 1 for acquired hemolytic anemia In the 6th patient, there was less justification for steroid therapy for supportive effect" in treating severe liver damage The experimental data supported the assumption that cortisone was responsible for the complications by bacterial infection The disease process in 1 of the patients corresponded to that seen in animal experiments in which an ordinarily nonpathogenic organism was able to invade and kill when the defenses of the host were lowered by cortisone This patient's tissues resembled those described in the animals, showing widespread microscopic abscesses with little tissue reaction One patient had histoplasmosis and 1 had monilia infection Both died The authors believe that the observations on these patients emphasize the numerous warnings of the hazards of cortisone therapy

Considerations of 3 Cases of Acute Meningitis in the Course of Cortisone Therapy F A Fusco Arch E Maragliano' pat e clin 12 977-999 (Oct) 1956 (In Italian) [Genoa, Italy]

Septic complications occurred in 6 patients in a group of 200 persons undergoing hormonal therapy Three of these 6 patients died of fulminating purulent nonmeningococcic meningitis while they were undergoing cortisone therapy—for acute subleukemic leukemia in the 1st patient, acute disseminated lupus erythematosus in the 2nd, and chronic lymphocytic leukemia in the 3rd The general condition of these patients was poor, agranulocytemia or severe granulocytopenia was present in their blood The meningeal localization in patients with septic complications is rare The authors believe that the infection was caused by a marked reversion of the immunoallergic responses of the organism, which is likely to take place in patients who are susceptible to toxic and infectious complications

Antileukemic Action of Reserpine A Goldin, R M Burton, S R Humphreys and J M Venditti Science 125 156 157 (Jan 25) 1957 [Washington, D C]

Since large doses of reserpine produce marked changes in the normal metabolic patterns, it was thought possible that this drug might alter the metabolism of tumor cells more extensively than it did that of normal cells and, thereby, prove detrimental to the tumor The data presented show that reserpine can exert an antileukemic action Hybrid male mice were inoculated in the right hind leg with 0 1 ml of a suspension of leukemic cells Leukemia was allowed to develop until the local tumor had reached a diameter of from 9 to 12 mm (estimated by palpation), at which time the disease is generally systemic as well as local The mice were then divided at random, and the designated groups were treated with a single injection of reserpine This produced an almost threefold increase in the survival time Inhibition of the growth of the local tumor was observed consistently in the reserpine-treated mice Five days after the administration of reserpine, when all control animals were dead the change in the mean tumor diameter was an inverse function of the dose of reserpine given Treatment with reserpine frequently appeared to result in complete disappearance of the local tumor at the site of leukemic inoculation, but transplantation of the spleen from several such mice resulted in leukemic growth, indicating that systemic infiltration had not been wholly suppressed Concomitant with the inhibition of local tumor growth, reserpine also appeared to retard the usual terminal leukocytosis in the peripheral blood Preliminary experiments indicate that a regimen of daily treatment with small doses of reserpine may be superior to treatment with a single large dose of the drug The mechanism by which reserpine exerts its antileukemic action is not known

Hepatic Coma Use of a New Drug, Arginine, in Its Treatment R Manning and M Delp J Kansas M Soc 58 18-20 (Jan) 1957 [Topeka]

Excessive accumulation of ammonia is an important factor in the metabolic disorders involved in hepatic coma, and, since 1-arginine hydrochloride had proved effective in protecting rats against toxic doses of ammonium acetate, the authors decided to use this substance on 3 patients with hepatic coma It was given intravenously All 3 patients recovered much more rapidly than had other patients treated with different methods None of the 3 patients received monosodium glutamate at any time, although other means of supportive therapy were given Arginine probably exerts its beneficial and protective effect by increasing the turnover rate of the classic Krebs-Henseleit urea cycle within the liver The authors recommend the use of arginine in the management of hepatic coma

Nicotinyl Alcohol Tartrate in Intermittent Claudication R O Gillhespy Brit M J 1 207-208 (Jan 26) 1957 [London]

Fifty patients with severe intermittent claudication secondary to generalized arteriosclerosis were given 1 25-mg tablet of nicotinyl alcohol tartrate or a placebo of identical appearance 4 times daily for at least 18 months Patients who had any other serious disease, correction of which might have influenced the assessment of the results, were excluded A blind-control trial of the drug was believed to be essential because of the difficulty of making an unbiased assessment of improvement in such a chronic condition At the end of the 18 months, only 30 patients remained for final assessment Fifteen patients had died, 3 had moved to another area, and 2 had refused to complete the course of treatment Of the 30 patients, 17 had received nicotinyl alcohol tartrate Ten of the 17 patients had had moderate improvement and 3 slight improvement, and in 4 the therapy failed None of the 13 control patients were even moderately improved, 4 were slightly improved, and 9 had no change Results in the patients who were given the active drug thus were significantly better than in those who received the placebo Nicotinyl alcohol tartrate is a useful drug in the control of intermittent claudication

PATHOLOGY

Drowning K Bowden M J Australia 1 39-43 (Jan 12) 1957 [Sydney, Australia]

On examination of the bodies of drowned persons, the usual signs of death from drowning are sometimes missing, and so a search has been made for some postmortem finding that is diagnostic of death from drowning Investigators demonstrated in animals that water might enter the blood stream by way of the pulmonary alveoli and might quickly reach the left side of the heart Attention was focused in fresh-water drowning on the possible dilution of the substances in the blood in the left side of the heart as compared with that in the right as an aid in the diagnosis of death from drowning Gettler's test on the difference in chloride levels in the two sides of the heart is mentioned, as is the work of Jetter and Moritz, who demonstrated that it is essential to determine what happens to the various constituents of the blood after death in ordinary cases in which death is not due to drowning They concluded that within from 6 to 12 hours after death there was a progressive fall in the blood chloride level and a rise in the magnesium level This has to be kept in mind when interpreting postmortem analysis of the blood constituents in cases of suspected drowning, and it imposes limitations on their use Observations on animals raise some interesting questions about drowning in man For example, is death in fresh-water drowning due to ventricular fibrillation brought about by the rapid flooding of the blood stream with water? Does the mechanism of death differ in fresh-water drowning from that in salt-water drowning in which ventricular fibrillation has not been so commonly observed? Could the rise in magnesium level in the blood in salt-water drowning of itself lead to death? In other words, are there additional factors? Is death in drowning a much more complex problem than simple asphyxia?

The author presents data on serum electrolyte levels in 6 patients drowned less than 4 hours previously in fresh water and in 5 subjects drowned in salt water The control series included subjects who had been dead for 5 to 36 hours as the result of hanging, a person dead from head injury, and several other subjects who had died suddenly less than 4 hours previously It was found that in fresh-water drowning and in salt-water drowning the changes in the electrolyte levels tend to be in opposite directions For example, the elevation of both sodium and chloride levels in salt-water drowning is not what one expects to find as a result of postmortem change and is in the opposite direction from the changes in sodium and chloride levels in fresh-water drowning This tendency toward changes in opposite directions indicates that asphyxia alone is not a common factor setting up the alteration

Provided that their limitations are appreciated, biochemical tests may be of value in the diagnosis of drowning It seems probable that, in some cases of salt-water drowning, cardiac arrest or ventricular fibrillation may rapidly set in as a result of the biochemical changes in the blood Hemolysis is a feature in some cases of fresh-water drowning Since drowning is a much more complicated process in many instances than simply deprivation of air or anoxia, is it necessary to do more than attempt to clear the airway and maintain artificial respiration? Is there a place for cardiac massage or the use of a defibrillator? Is intravenous therapy necessary? Additional treatment along these lines in some instances appears to be largely impracticable, but it is not necessarily so Since drowning is a complicated process and more difficult to treat than is generally known, learning to swim should be a part of every child's education

Tumors of the Vascular System with Special Reference to Malignant Angio endothelioma D J Reddy, K G Gupta, T S Rao, an others Indian J Dermatol & Venereol 22 165-174 (Oct-Dec) 1956 [Bombay, India]

Of the patients with hemangiomas and lymphangiomas on whom the authors made clinical and histological studies, 18 with hemangiomas and 3 with lymphangiomas presented no unusual features However, 4 endotheliomas were malignant and 4 others showed clinical and histological findings bordering on malignancy Two of the vascular tumors were of the sclerosing type of angioendothelioma that are likely to be mistaken for fibromas While the ages of the patients ranged from two months to in the 7th decade, 40% of the hemangiomas occurred in children less than 10 years of age The malignant endotheliomas, however, with one exception (a 2-year-old-child), occurred in patients between the 3rd and 7th decades

In commenting on 4 patients with lesions on the borderline of malignancy, the authors say that pathologists have noted that, despite evidence of malignancy, few of these tumors metastasize, although surgeons are familiar with the benign metastasizing angioendothelioma These contradictory findings are a warning against dogmatism on the part of the pathologist and the clinician The unpredictable biological behavior of angioendothelioma should be realized The influence of trauma in the production of tumors of the vascular system is well established The authors believe that intramuscular injections in the gluteal region in one of the reported cases, constant injury to the mucosa and structures beneath it by a protruding canine tooth in another, and a cut over the chin sustained by another patient were probably responsible for the neoplasms at these sites Chronic inflammatory reaction that followed ulceration of the angioendothelioma over the scalp may have given the histological picture of borderline malignancy

Residual Radiologic Findings in Patients with Pulmonary Tuberculosis Treated with Tuberculostatic Drugs Interpretation as a Function of Anatomic Examinations G Brouet, J Marche and J Chretien Rev prat 7 233-246 (Jan 21) 1957 (In French) [Paris]

A series of 1,800 lung specimens that were removed surgically from patients who had pulmonary tuberculosis and who had been treated with tuberculostatic drugs were examined macroscopically and microscopically Of these, 40 demonstrated the efficiency of this treatment as revealed by a biological cure of the tuberculosis An operation had been performed on each of these patients for 1 of the following 3 reasons 1 The patient wanted to be freed from a residual minor abnormality revealed by the chest roentgenogram, because this abnormality required careful observation after prolonged treatment 2 Although the roentgenograms taken after the treatment with the tuberculostatic drugs showed almost complete clearing of the lungs, the 1st roentgenograms taken before the institution of the treatment had shown such severe tubercular lesions that caution seemed to be warranted in pronouncing the recovery complete In patients belonging to these 2 groups, complete healing of the tuberculous foci in the absence of any nonspecific, significant, and residual alterations may be observed frequently on microscopic examination Fourteen of the 40 specimens were from patients in 1 of these 2 groups 3 Roentgenograms revealed important residual abnormalities after a more or less prolonged treatment with the tuberculostatic drugs, or the appearance and the size of the lesions in the roentgenogram did not warrant a favorable prognosis The findings suggested the persistence of active tuberculous foci despite constantly negative bacteriological findings The anatomic examination of the removed specimens, however, showed that the radiologic interpretation had been erroneous and confirmed the efficiency of the antituberculous chemotherapy Twenty-six of the 40 specimens were from patients in this group

The macroscopic and microscopic examination of the 14 specimens did not show any residual tuberculous foci in the pulmonary parenchyma Microscopic examination revealed either a systemic, pure, diffuse or localized sclerosis or air-containing structures free of any tuberculous activity These air containing structures had been interpreted erroneously as tuberculous cavities in the roentgenograms They were rarely the result of a vesicular emphysema around the lesions but more often resulted from extensive bronchiectases of an entire segment or lobe, but they were free of any active or associated bronchial tuberculization Cicatricial cavities were observed frequently The same changes were observed in the 26 specimens, but one or several inactive tuberculous foci persisted The patients with these findings, nevertheless, had made a clinical recovery These foci were completely involuted and very small, and the anatomic changes were not characteristic of tuberculosis There were no exudative or follicular lesions in the adjacent parenchyma

The macroscopic and microscopic examinations of lung specimens removed surgically make possible a better interpretation of roentgenograms that show residual changes in patients treated with tuberculostatic drugs They also show that a total anatomic recovery is possible in some patients after sufficientl prolonged chemotherapy (for 12 months in patient with recent common forms of pulmonary tuberculosi and for from 18 to 24 months in patients with sever initial or untreated old lesions) A cure of pulmonar tuberculosis treated accordingly may be obtained wit radiologic sequelae that do not necessarily indical active lesions

Struma Ovarii A Follow up Study of 20 Cases (Aberrant Thyroid Tissue III) J B Dalgaard and P Wetteland Acta chir scandinav 112 1-15 (No 1) 1956 (In English) [Stockholm]

A total of 62,000 biopsy specimens were examined for evidence of aberrant thyroid tissue, which was found in the ovary of 20 patients, 107 patients with ovarian teratoid tumor were treated, and varying amounts of thyroid tissue were found in the 21 specimens taken from the 20 patients Follow-up examinations were made from 1 to 21 years after the ovarian operation Small amounts of thyroid tissue (struma ovarii spuria) were present in the tumors of 7 patients, whose ages were between 25 and 47 years Six tumors revealed ordinary follicular thyroid tissue, and 1 displayed a papillary pattern The symptoms were nonspecific Ascites was present in 1 patient who had a nontoxic cervical goiter and exophthalmos She died of metastasizing mammary carcinoma 13 years after an ovarian operation The 6 other patients were in good health Thyroid tissue (struma ovarii vera) was the only or the predominant finding in 13 patients All showed ordinary follicular thyroid tissue in the ovarian tumor The ovarian struma proved to be of little or no clinical importance in 7 of these patients Ascites occurred in 3 and peritoneal adhesions in 5 patients All were alive and well at follow-up examination

The 6 remaining patients showed specific or severe symptoms One had a fully developed Meigs's syndrome cured by removal of the ovarian tumor Thyrotoxic symptoms due to functioning ovarian strumas were found in 3 patients The basal metabolic rate showed a permanent return to normal after the ovarian operation in only 1 of these patients Two had malignant ovarian struma A papillary thyroid carcinoma was first removed from 1 ovary and 7 years later from the other in 1 of these patients She was still alive 4 years later Bony metastases were found 4 years after removal of the ovarian struma in the other of the 2 patients The patient had an extraordinarily protracted course of the disease and died 21 years after operation Severe symptoms are most likely to develop in patients with pure ovarian struma and in those with a papillary pattern Long observation of patients with ovarian struma is necessary Women with thyrotoxic symptoms should be subjected to gynecologic examinations, especially when no cervical goiter is present, before an operation on the thyroid is performed

Metastatic Thyroid Tissue in Bones as Diagnostic Problem A Follow-up Study of 5 Cases (Aberrant Thyroid Tissue IV and Conclusion)' J B Dalgaard and P Wetteland Acta chir scandinav 112 18-24 (No 1) 1956 (In English) [Stockholm]

A follow-up study was made of 5 women whose biopsy specimens revealed thyroid tissue with or without histological atypia Five specimens were obtained from bones and 1 from the scalp, but even this latter was possibly of osseous origin Two patients had spontaneous fractures of the femur and humerus respectively Histological examinations showed metastatic adenocarcinoma with marked atypia and colloid-filled follicles of thyroid type Death occurred within 1 year after the biopsy Two patients with metastasizing thyroid adenoma died 2½ years after diagnostic biopsy One patient, whose primary tumor was a papillary ovarian struma, died 17 years after the 1st osseous biopsy had been made A remarkable clinical improvement was observed in 1 patient with a metastasizing sternal Hurthle cell carcinoma After subtotal thyroidectomy a Hurthle cell adenoma recurred twice in the right lobe of the thyroid In the presence of the sternal metastasis, the thyroid lesion was considered malignant The patient responded well to radiologic and I^{131} treatment The sternal metastasis subsided, and the patient was found in good health at the follow-up examination 2 years later The histological diagnosis of metastases from a thyroid tumor was unexpected in 3 of the patients, since no symptoms of thyroid disease were present and since the goiter of 1 patient had been considered benign The diagnosis of malignant thyroid disease was first revealed by means of the osseous biopsy in all these patients An apparently benign structure of the aberrant node, called usually metastasizing adenoma,' should not deceive the physician This term is mostly used for adenomas occurring in bones but also for those located laterally on the neck The authors suggest abandoning this term, since it may be misleading when used uncritically and may mask the malignant nature of the lesions

RADIOLOGY

Splenoportography in Forty seven Patients L P Doutre Bordeaux chir, pp 210-213 (Oct) 1956 (In French) [Bordeaux, France]

Transparietal splenoportography was performed on 47 patients with various types of splenic and hepatic disease The author emphasizes the absence of risk associated with splenic and even extrasplenic puncture One patient with gastric cancer was operated on on the morning splenoportography was performed because of suggested hepatic metastasis No hemorrhage occurred One patient with cancer of the rectum was erroneously given a puncture into the peritoneal cavity He underwent operation on the next morning because the iodized preparation was completely absorbed by the peritoneum without serious accident Transparietal splenoportography permits evaluation of the changes in the splenoportal trunk Splenoportography should always be performed before splenectomy In doubtful cases splenoportography might indicate whether surgical or medical treatment is necessary

Roentgenologic Aspects of the Eisenmenger Complex C L Ebnother and H L Abrams Am J Roentgenol 77 248-262 (Feb) 1957 [Springfield, Ill]

Roentgenologic studies were performed on 6 male and 6 female patients between the ages of 4 and 34 years with the Eisenmenger complex, a congenital malformation consisting of a large ventricular septal defect, with aortic overriding of variable degree, increased pulmonary vascular resistance and consequent pulmonary hypertension and a shunt of blood from the right ventricle into the aorta Cyanosis, from slight to moderate in degree, was present in all but 1 patient Exertional dyspnea was a common complaint, and recurrent respiratory infections were present in 8 patients Four patients had a history of frequent severe bouts of pneumonia Clubbing was noted in 6 patients, and all patients had murmurs, usually systolic but occasionally diastolic as well, varying in location intensity, quality, and radiation The most constant roentgenologic features were right ventricular enlargement, enlargement of the main and hilar pulmonary arteries, and disparity between the large size of the proximal pulmonary arteries and the small caliber of the peripheral pulmonary arteries The aorta appeared hypoplastic in 9 of the 12 patients The roentgenographic appearance associated with pulmonary hypertension in congenital heart disease is frequently distinctive, this is well illustrated by studies of the Eisenmenger complex

The Eisenmenger complex must be differentiated from all conditions associated with pulmonary hypertension including atrial septal defect, ventricular septal defect, patent ductus arteriosus, and primary pulmonary hypertension Usually there is greater right ventricular enlargement and evidence of pulmonary plethora, with prominent peripheral vessels, in patients with atrial septal defect Biventricular enlargement with more obvious left ventricular prominence than that in the Eisenmenger complex may be observed in patients with a large ventricular septal defect The absence of cyanosis and significant arterial oxygen unsaturation are important differential points in patients with atrial septal defects and in those with ventricular septal defects Angiocardiography and peripheral blood oxygen studies are important for differentiation in patients with patent ductus arteriosus and primary pulmonary hypertension

The Roentgenologic Diagnosis of Pulmonary Hypertension in Mitral Stenosis J B Schwedel, D W Escher, R S Aaron and D Young Am Heart J 53 163-170 (Feb) 1957 [St Louis]

The widths of the right descending branch of the pulmonary artery were measured with the aid of teleroentgenograms in its upper portion (at right angles to the bronchus from the bronchus to the outer margin of the vessel) in 100 normal hospital employees between the ages of 18 and 60 years Ninety per cent of the widths were from 9 to 13 mm Only 4 were 15 mm or greater, and all of these were in the 40-year to 60-year age group Thus the range from 9 to 13 mm may be considered normal, and measurements exceeding 14 mm may be considered abnormal

The widths of the right pulmonary artery were measured in 105 patients with pure or significantly predominant mitral stenosis Roentgenograms revealed decreased aeration of the lung parenchyma in 70 of the 105 patients and showed narrowing of the tertiary pulmonary artery in 21 Pulmonary artery pressure levels were obtained by cardiac catheterization in 77 and by direct puncture of the pulmonary artery in 56 The upper limit of normal mean pulmonary artery pressure is regarded as 15 mm Hg, and a mean pressure level of 25 mm Hg is considered a significant elevation Of the 77 catheterized patients, 47 had right pulmonary artery widths measuring 14 mm or above Forty-five of the 47 had resting mean pulmonary artery pressure levels exceeding 25 mm Hg and the other 2 had less significant elevations All of the 41 patients with pulmonary artery widths of 15 mm or more had significant pressure elevations A similar correlation was noted between pulmonary artery widths and pulmonary artery pressures obtained at the time of operation by pulmonary artery puncture In patients with widths of below 14 mm, correlation was much less reliable Thirteen of the 77 catheterized patients had neither increased right pulmonary artery widths nor significantly increased pulmonary artery pressure levels Seventeen others among the catheterized patients showed significant pulmonary hypertension with pulmonary artery widths of 13 mm or less

These observations show that roentgenographic demonstration of right descending pulmonary artery widths of 15 mm or more is definitely associated with significant pulmonary hypertension, and significant pulmonary hypertension is most likely present in patients with widths of 14 mm A linear correlation between pulmonary artery width and level of pulmonary artery pressure does not exist

Cardiac Ventriculography Direct Transthoracic Needle Puncture Opacification of the Left (or Right) Ventricle J S Lehman, B G Musser and H D Lykens Am J Roentgenol 77 207-234 (Feb) 1957 [Springfield, Ill]

The term cardiac ventriculography' was coined by the authors to designate a procedure of direct transthoracic needle puncture of the heart for the purpose of effecting opacification of the left or right ventricle Seventy-seven cardiac ventriculographies were performed on 60 patients for the assessment of the presence and degree of mitral valvular insufficiency, the evaluation of surgical procedures directed towards correction of mitral insufficiency, appraisal of aneurysm of the left ventricle and assessment of certain aortic lesions, such as aortic aneurysm or coarctation The patients were given a combination of secobarbital or pentobarbital, atropine sulfate, and meperidine (Demerol) hydrochloride 1 hour before the examination to allay apprehension and pain and to aid in preventing certain potential disturbances of cardiac conduction A 70% solution of iodopyracet (Diodrast) was used as radiopaque medium

Roentgenologic technique, ventricular puncture, intracardiac pressure and electrocardiographic monitoring, and injection of the contrast medium are discussed The intracardiac pressures observed and the electrocardiographic changes that occurred in the course of the procedure are presented Inadvertent intramyocardial or intrapericardial infiltration of iodopyracet occurred in 8 patients Slight pain but no shock symptoms, a 6-beat, 7-beat, or 9-beat ventricular tachycardia, atrioventricular dissociation, and right bundle-branch block were observed in 7 of these patients, the electrocardiographic changes persisted through the immediate postinjection period in some of the patients A complete heart block occurred in one patient and persisted for 4 months causing aggravation of the patient's mitral insufficiency These reactions to the procedure occurred among the first 47 persons given cardiac ventriculographies They were avoided later by the aiming of the needle, adjustment of the needle point, shallow breathing of the patient, and nonmotion of needle or patient after intracardiac insertion of the needle

An evaluation of the quality of the cardiac ventriculographies based on the degree of contrast visualization of the ventricle is tabulated Atrial fibrillation, with a poorly controlled ventricular rate, paroxysmal atrial tachycardia, atrial tachycardia caused by a vagal release from administration of atropine, and ventricular tachycardia, either spontaneous or induced by medication, are contraindications to cardiac ventriculography The procedure should not be employed in children and infants because of the greater likelihood of intramyocardial injection of the contrast medium i e , when the ventricular cavity is small

PHYSIOLOGY

Pulmonary and Circulatory Effects of Acute Pulmonary Vascular Engorgement in Normal Subjects S Bondurant, J B Hickam and J K Isley J Clin Invest 36 59-66 (Jan [Part I]) 1957 [New York]

Central and pulmonary vascular engorgement is a characteristic feature of congestive heart failure It has been suggested many times that this vascular engorgement might be responsible for certain phenomena associated with congestive failure, such as stiffening of the lungs, dyspnea, and orthopnea The simultaneous occurrence of pulmonary edema and other changes, however, has made it difficult to single out the effects of simple vascular engorgement The present study was undertaken to investigate the pulmonary and circulatory effects of acute reversible central and pulmonary vascular engorgement in normal men Central and pulmonary vascular engorgement was produced by rapid application of pressure over the surface of the body Two methods were used to accomplish this inflation of an aviator's 'G suit' and submersion in water while the patient was breathing against atmospheric pressure The G suit was a single-chamber, balloon-type garment that covered the feet, legs, and lower part of the abdomen The suit could be inflated to the desired pressure within 5 seconds by a standard Air Force G-valve Suit pressure of 2 lb per square inch (103 mm Hg) was customarily used The subjects were studied in the seated position before, during, and after a 2-minute period of suit inflation Seated subjects were studied before, during, and after submersion in water to the neck and with the head just below the surface At this depth, the mean pressure at hip level during total submersion was about 60 mm Hg or 1 2 lb per square inch

G-suit inflation produced in 15 subjects an increase in central venous pressure of 26 8 (standard deviation ± 7 8) cm H_2O and a fall in compliance distensibility from the control value of 0 217 ± 0 048 liters per centimeter of water to 0 093 ± 0 036 liters per centimeter of water A similar drop in compliance occurred with submersion On maintenance of G-suit pressure or submersion for a 2-minute period, central venous pressure and compliance showed a progressive, but incomplete, return toward control levels Infusion of norepinephrine or immersion of an arm in ice water during this time prevented the return of venous pressure and compliance toward control levels Administration of norepinephrine or immersion of an arm in ice water with G-suit inflation caused a moderate increase in central venous pressure and a moderate decrease in compliance When the G suit inflated during norepinephrine infusion, the resultant elevation of central venous pressure and the drop in compliance were greater than in untreated subjects Pretreatment with hexamethonium diminished the rise in central venous pressure that occurred with G-suit inflation but did not affect the compliance changes It is suggested that the compliance changes induced by these procedures depend, at least partially, on varying degrees of pulmonary vascular engorgement and that this, in turn, depends partially, under the present experimental conditions, on peripheral venous tone

Some Respiratory Data in Man at the Barometric Pressures of 760, 526, and 379 mm Hg A Scano, F Rossanigo, G Meineri and B Tagliamonte Riv med aeronaut 19 595 605 (Oct Dec) 1956 (In Italian) [Rome]

The authors report on the results obtained in a group of 35 jet pilots with an average age of 25 years who were subjected for 30 minutes to simulated flights in a decompression chamber with barometric pressures of 526 and 370 mm Hg corresponding to elevations of 3,000 and 5,500 m respectively The pulmonary ventilation, the alveolar ventilation, and the respiratory rate at rest were recorded at sea level and at the above-mentioned barometric pressures Samples of mean alveolar air were collected and analyzed The respiratory responses to a hypoxia of medium degree were as follows no increase of the respiratory rate, a nonsignificant increase of 2 2% in the pulmonary ventilation at 3 000 m , a significant increase of 23 4% at 5,500 m , and a relatively higher increase of the alveolar ventilation of 4 3% and 31 2% respectively, with the same statistical value The values of pAO_2 and $pACO_2$ and respiration obtained experimentally and with statistically significant variations, when plotted on the oxygen-carbon-dioxide diagram, result in a curve that falls between the curve for nonacclimatized subjects and that for acclimatized subjects They correspond to a physiological altitude somewhat lower than the barometric altitude and coincide with the alveolar ventilation and with the energetic metabolism of the subjects A correlation corresponding to —48 8% was found between the values of volume of alveolar air and $pACO_2$ at the different altitudes The authors emphasize the meaning of these respiratory variations for a careful and exact evaluation of the functional responses to lowered barometric pressures

BOOK REVIEWS

Heart Sounds, Cardiac Pulsations, and Coronary Disease By William Dock M D Professor of Medicine State University of New York College of Medicine at New York City Porter lectures series 21 Cloth $2 50 Pp 98 with 23 illustrations University of Kansas Press, Lawrence, 1956

In the first two chapters of this small volume, the author presents his views on the value of the ballistocardiogram, pulse records, and heart sounds in diagnosis, prognosis, and treatment The last chapter deals with the controversial subject of the relationship of exogenous cholesterol and cigarette smoking to coronary artery disease The author is positive in his belief that the increasing incidence of coronary artery disease in this country, particularly in the younger age groups, is to a large extent due to a diet high in cholesterol As to smoking, he states, "The enormous rise in consumption of cigarettes explains in part why coronary disease kills men at an earlier age in 1955 than it did before 1900 Long years of experience as a teacher, research worker, and lecturer have enabled Dr Dock to present his views in a convincing manner, even though many cardiologists will disagree with him

California Social Welfare Legislation, Financing, Services, Statistics By Vaughn Davis Bornet, Ph D Research study commissioned by Commonwealth Club of California founded 1903 Cloth $5 Pp 524 with 8 illustrations Prentice-Hall Inc Englewood Cliffs N J 1956

The purpose of the book is to provide the citizen, social worker, and specialist in social studies with comprehensive statistical data on California's social welfare programs, their legislation financing, and services Although the presentation of information on a county basis is a primary objective of the work, the functions of larger political and economic units are not overlooked The first two chapters (part 1) deal with the state and federal setting as well as with California's 10 economic regions Legislation, covered in part 2, is basic to the various programs Its complexity is a feature emphasized by the many amendments to California's laws Usually the most important parts of the laws are quoted verbatim, yet, despite frequent mention of the 25th amendment to the California constitution, no quotation or concise paraphrase of its provisions is given

Part 3, on financing, will interest both students and taxpayers The relative growth and importance of public and private welfare programs are carefully examined for the years 1950 to 1954, some data for selected years in the mid-1920's are also included The increase in private charities over the 30-year interval was substantial, yet that in public welfare was apparently three or four times as great More frequent use of the ratio of financial assistance to total disbursements, as in table O, for both public and private programs would have been desirable

Part 4 contains five chapters, the third of which deals chiefly with health services for children and adults The remaining chapters delineate other categories of welfare services provided to four different age groups The author acknowledges that this part "could not be exhaustive in the manner of some parts of the volume,' as it deals with only four counties in northern California The findings may not be useful for other parts of California, or the nation, because of the dissimilarity of these larger units with respect to organized social welfare As indicated in parts 3 and 5, this same problem of heterogeneity is evident in the financing of welfare programs in California

Although component data for public assistance expenditures, as shown in table C, are provided for all counties in the part (5) assigned to social welfare statistics, those for health and recreation as well as welfare (public assistance) are presented for only one county and one city (tables F and G) Evidently the degree of variation in the extent and type of data concerning public health is great at the county level Within the public assistance categories, of which aid to the blind is one, a small amount of health expenditures is included under general relief (footnote d of table C) For the five Bay Area counties (table 1, page 300), 30% of the total public expenditure for health, welfare, and recreation in 1954 was for health Chiefly because of the more rapid rise in welfare expenditures during the last 30 years, the proportion spent on health has been declining

The author evidences honesty of scholarship in many ways References to other works and sources of information are amply provided The cost data are often presented on a per capita basis and also adjusted for changes in the value of the dollar Generally the author displays a critical attitude toward his data, realizing that the assignment of identical names to certain data does not necessitate identical meaning In similar fashion the reader should watch for the variations in the major expenditure categories among tables C, D, and F With equal frankness the author recognizes, in addition to the world of "organized social welfare which is the subject of this volume, another world of charity 'almost impossible to measure He characterizes his volume as an overview, not an encyclopedia It does not question motivation and wisdom, attempt definitive comment on welfare needs, or call for a review of programs It seeks merely to record facts

Although some readers may not consider the author's arrangement of the data optimal at all times, this work provides a significant step toward the accumulation and presentation of systematic data on the basis of which social welfare programs can be evaluated and improved in the interest of both donors (voluntary and involuntary) and recipients

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated

Classics in Arterial Hypertension By Arthur Ruskin, M D F A C P Associate Professor of Internal Medicine, University of Texas—Medical Branch, Galveston Publication Number 290 American Lecture Series monograph in Bannerstone Division of American Lecture Series Classics in Science and Medicine Edited by Wiktor W Nowinski Ph D, Dr Phil Nat, Associate Professor of Biochemistry University of Texas—Medical Branch Cloth $9 50 Pp 358 with illustrations Charles C Thomas, Publisher 301-327 E Lawrence Ave Springfield Ill Blackwell Scientific Publications Ltd, 24 25 Broad St Oxford England Ryerson Press 299 Queen St, W Toronto 2B Canada, 1956

The aim of this anthology is to accumulate in one convenient volume past eminences and peaks of achievement in the field of hypertension Older merely allusive pre-Halesian material is briefly surveyed in the introduction The next 120 pages deal with methods from Hales to Korotkov and the remainder with clinical and physiological descriptions ending with Goldblatt's description of experimental renal hypertension in dogs The selections are well arranged so that the book is both informative and inclusive Everyone will not agree with Dr Ruskin's opinion that hypertension due to buffer nerve section (Koch and Mies, 1929) is transitory although he says that it is labile

The failure to include quotations from Janeway's book has the reasonable explanation that that book has no priority, for credit for the material therein goes to Allbutt and before him, to Mahomed Nevertheless Janeway's book had a profound influence on medical thinking in this country and, in particular popularized the term hypertension as more convenient than Allbutt's etymologically superior term 'hyperpiesia' Perhaps a selection from Janeway should be included and Potain, whose contribution was not large omitted This book will interest all reflective physicians who work with some aspect of hypertension

Notions de cytologie et histologie Par M Chevremont professeur ordinaire aux Facultes de medecine et des sciences de l Universite de Liege Boards Pp 994, with 636 illustrations Editions Desoer 21, rue Sainte-Veronique Liege Belgium 1955-1956

This first edition in print is the successor to two editions in other forms prepared for students of zoology of the medical sciences, and of natural science at the University of Liège It deals primarily with the cytology and histology of the higher vertebrates A general introduction describes some of the most important techniques and contains much interesting information about electron microscopy, phase-contrast microscopy tissue-culture methods, histochemistry, histophotometry, differential centrifugation, and so on The three major sections that follow are devoted to the cell, to the structure of tissues, and to the aggregation of cells into organs and systems

The outstanding feature of the book is the abundance and magnificence of its illustrations These include some especially instructive diagrams, many stained sections beautifully reproduced in color, and some striking electron micrographs In many illustrations, unfortunately, the labeling imposes unnecessary strains on the eyesight and the patience of the student by making it necessary to match numbers or letters in the figure against their counterparts in the legend The method of direct labeling that has become practically universal in textbooks of gross anatomy deserves to be adopted also in microscopic anatomy, and in the present book it would occasionally result in actual saving of space The text is readable and interesting and there is a good index

Allergic Dermatoses due to Physical Agents Edited by Rudolf L Baer M D Associate Professor of Clinical Dermatology and Syphilology New York University Postgraduate Medical School New York [This material was published in *American Practitioner and Digest of Treatment* for August 1956] Cloth $3 Pp 110 with 3 illustrations New York University Press New York distributed by J B Lippincott Company 227-231 S Sixth St Philadelphia 5 2083 Guy St Montreal Canada Pitman Medical Publishing Co, Ltd 39-41 Parker St Kingsway London W C 2 England 1956

This is a small book containing six articles, each by a different contributor and each devoted to a different aspect of the general subject Dr Baer discusses the present status of differentiation of allergic and nonallergic hypersensitivity to physical agents, Dr Allan Lorincz contributes a chapter on hypersensitivity to trauma Dr Herman V Allington writes on eczematous and polymorphous hypersensitivity to light Dr Stephan Epstein discusses urticarial hypersensitivity to light, Dr Otis F Jillson takes up hypersensitivity to heat, and Drs Sylvia Griem and Stephen Rothman discuss cutaneous sensitivity to cold Each chapter has an up-to date bibliography It is questionable whether many of the conditions discussed arise on an allergic basis, but the contributors indicate the difficulty of coming to a decision concerning this The book is singularly free from typographical errors The only criticism is that the title on the cover of the book is merely Allergic Dermatoses, which is slightly misleading, in view of the limited scope of the monograph The book is highly recommended to dermatologists, allergists, and others interested in the cutaneous expressions of altered reactivity to physical agents

An Atlas of Diseases of the Eye Compiled by E S Perkins M B, F R C S and Peter Hansell M R C S F R P S Director, Departments of Illustration and Photography Westminster Medical School and Institute of Ophthalmology University of London With foreword by Sir Stewart Duke-Elder, K C V O, M A D Sc Cloth $10 Pp 91 with illustrations Little Brown & Company, 34 Beacon St Boston 6 J & A Churchill, Ltd 104 Gloucester Pl Portman Sq London W 1, England, 1957

It would require either an extensive private practice or affiliation with a very large charity institution to see and constantly keep in mind the fundus appearances in all systemic, local, and congenital ocular diseases Hence this atlas should be a welcome addition to any ophthalmologist's library The pictorial representations of normal, trivial, and abnormal findings in the fundi are supplemented by a lucidly and concisely written text The colored photographs and the drawings illustrating the important features of eye conditions are excellent This compact, beautifully illustrated, and well-written book should prove of value to the medical student, the general practitioner, the ophthalmological resident, and the ophthalmological clinician and teacher

QUERIES AND MINOR NOTES

ENDOMETRIAL HYPERPLASIA AT SIXTY YEARS OF AGE

To the Editor —*A 60 year-old woman has had three episodes of moderate uterine bleeding in the past six weeks Examination revealed a slightly enlarged uterus, which was corroborated by passing a sound The ovaries were not palpable Curettage was done The pathologist reported that there was some hyperplasia of the endometrium of adenomatous type and that this is a precancerous condition The patient had several bouts of hypertension over the past few years, but the blood pressure has stabilized at 140/80 to 170/90 mm Hg for the past six months Should she have a hysterectomy?* *M B , Canada*

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —Hyperplasia of the endometrium in a woman 60 years old is always significant, assuming that she has had no estrogen therapy Stimulation of the endometrium at this time of life may be the result of ovarian pathology in the form of a steroid-producing tumor, such as the granulosal neoplasm Novak has suggested that endometrial hyperplasia in the postmenopausal period may have carcinogenic implications in that there is a frequent coexistence of the two conditions

If this patient has a recurrence of her uterine bleeding, a complete hysterectomy and bilateral salpingo-oophorectomy is indicated If there is no further bleeding she should be kept under observation, and, if there is any change in her pelvic findings, surgery should be carried out

Answer —In seeking the cause for this patient's uterine bleeding, one considers malignancy, sex steroid stimulation, either intrinsic or extrinsic, benign tumors, and infection Infection and benign tumors are ruled out, the ovaries are "not palpable,' which somewhat lessens the possibility of a functioning tumor of the ovary, but one must definitely ascertain whether the patient has been taking any endocrine preparation If the bleeding is caused by hyperplasia of the endometrium, there is some basis for this histological change in the endometrium The pathologist's description of "hyperplasia of the endometrium of adenomatous type suggests that there is less stromal hyperplasia than is usually found The association of adenocarcinoma of the endometrium and endometrial hyperplasia is noteworthy The inquirer asks whether a hysterectomy should be performed, this consultant's answer is yes There are certain "ground rules, tissue committee studies, and other justifiable restraints, but most resolve into how many uterine curettages should be done before laparotomy is performed This patient should have a complete hysterectomy and bilateral salpingo-oophorectomy, provided that any endocrine therapy is ruled out

ABSENT PULSE WITH NECK BRUIT

To the Editor —*A 42-year-old man suffered a hemiplegia on the right side two years ago and made a good recovery with exception of moderate weakness of the involved extremities and a mild degree of aphasia Because he could not continue with his usual work and light work was not available to him, he has spent most of his time sitting about at home In the past year he has had episodes of syncope associated with change of position or prolonged standing he was treated with Neo-Synephrine (1 25 mg capsule three times a day) and Dexamyl (twice a day), with some improvement The patient's pulse is unobtainable at the right wrist, and a bruit is heard over the middle of the right sternocleidomastoid muscle There is reason to feel that these findings were not present prior to his stroke, although they were not picked up until six months afterward Cerebral arteriograms were negative, and the results of routine laboratory studies were not remarkable Blood pressure is normal as obtained in the left arm but unobtainable in the right The optic fundi are not remarkable What is the possible relation of the murmur in the neck and the absent radial pulsation in the right arm to the hemiplegia that occurred? Please give further suggestions relative to maintaining better vasomotor tone in this individual* *M D , Ohio*

This inquiry was referred to two consultants, whose respective replies follow —Ed

Answer —The absence of the radial pulse on the right side is undoubtedly due to some impaired circulation in the right arm This impairment, evidently, can be traced high up in the arterial tree and involves the large arterial trunks The fact that he has no blood pressure on the right side is confirmatory evidence that the circulation does not come through the right brachial artery An explanation for this impairment requires some comment It could be due to a gradually developing thrombosis of the brachial, the axillary, or the subclavian artery There is no mention made as to whether the subclavian pulse could be elicited on palpation It is doubtful whether the impaired circulation can be attributed to a marked arteriospasm in the absence of any history of a penetrating wound or some trauma It is possible to develop a gradual thrombosis of the brachial or axillary artery (crutch

---

The answers here published have been prepared by competent authorities They do not however represent the opinions of any medical or other organization unless specifically so stated in the reply Anonymous communications and queries on postal cards cannot be answered Every letter must contain the writer's name and address, but these will be omitted on request arteritis) but there is no history of the patient s using crutches The impaired pulse probably cannot be attributed to the hemiplegia per se If the cause of the bruit in the neck on the right side can be determined, this may explain the impaired circulation in the arm and could explain the hemiplegia The bruit could be due to an aneurysm involving the large arterial structures the carotid or innominate artery An aneurysm could be due to either syphilis a toxic infectious condition or arteriosclerosis However aneurysms may develop as a result of some indeterminate factor When one aneurysm is present it is quite possible that another may exist in the vascular structures in the brain which could explain the hemiplegia, but according to the query the studies of the brain were unrevealing The bruit may be due sometimes to an arteriovenous fistula However such conditions are either congenital or acquired If it was acquired, there should be some history of a penetrating wound If it is congenital then it certainly is in an unusual site and would have been detected much earlier Perhaps there is a history of rheumatic heart disease, such a patient might have a dilated auricular appendage, in which area an embolus may develop and lodge into the brain area This consultant has seen this happen in two or three instances in younger patients, in whom hemiplegia could not be explained in any other manner Since this patient apparently made a good recovery except for moderate weakness of the involved extremities he should be encouraged to get about Physical therapy should be carried out and, if this patient is in a large center where there are some rehabilitation clinics that can give him the benefit of modern therapy, this would be very helpful If there is much general weakness and if the blood pressure is low, 10 mg of Ritalin two or three times a day may be helpful

Answer —This patient appears to have occlusion of the right subclavian artery and possible partial occlusion of the common carotid This could explain the absence of pulsations in the right arm and the bruit in the neck The findings in the right arm and neck are probably unrelated to the hemiplegia, but both may be the result of primary diffuse vascular disease such as atherosclerosis or arteritis An atherosclerotic plaque could occlude the right subclavian artery and partially occlude the common carotid However, it is most unusual to have atherosclerosis as a cause of upper extremity occlusion in a man as young as this Embolism is a more common cause for upper extremity arterial occlusion in a man of 42 This could also explain the hemiplegia as well as the bruit in the neck, which would occur if the common carotid were only partially occluded On the other hand, there is no evidence of a source for the embolus in the history and apparently in the examination However, blood clotting on a plaque in the ascending aorta and then being swept distally might explain the symptoms The possibility of early pulseless disease should be considered Paradoxic embolism from clots in leg veins going through a patent foramen ovale is a rare cause of emboli for which a source is not present in the heart At any rate, it would appear to be worthwhile to start anticoagulant therapy, with the patient ambulatory In addition, a low-fat and low-cholesterol diet may be indicated

In regard to the maintaining of vasomotor tone to prevent the syncopal episodes, this patient may be benefited by the use of an elastic support that covers not only both lower extremities but also the waist This type of support is obtainable from the Jobst Institute, P O Box 653, Toledo 1, Ohio, and is usually worn by patients who have extreme edema up to the hips The support may prevent the dumping of blood into the lower extremities when the patient sits up or stands Air-inflated suits are also obtainable, if the symptom is an incapacitating one The patient should also learn to sit up or stand up very gradually to allow time for adjustment of vasomotor reflexes

CONGENITAL THROMBOCYTOPENIC PURPURA

To the Editor —*The mother of an infant with congenital thrombocytopenic purpura is anxious for another baby What are the chances of this recurring?*

Ralph W Morrison Jr , M D , Johnstown, Pa

Answer —Congenital thrombocytopenic purpura occurs infrequently, but the literature contains many case reports and studies bearing on its pathogenesis It appears in infants born (1) of mothers with idiopathic thrombocytopenic purpura who either have had a splenectomy or are symptomless and unaware of a lowered platelet content (2) of normal mothers, and (3) of mothers with drug-induced thrombocytopenic purpura such as follows the ingestion of quinine

Current concepts implicate an immunoallergic mechanism in the causation of the disease in the infant For the mother with idiopathic thrombocytopenic purpura the transplacental passage of antibodies occurs into the fetal circulation These antibodies consist of autoagglutinins for the platelets of the mother and infant as well as isoagglutinins for each other s platelets In the case of a normal mother it has been postulated that she develops isoagglutinins for the baby s platelets, presumably on the basis of platelet incompatibility between mother and infant in a manner similar to erythroblastosis She may also have been sensitized to platelet antigen in a previous transfusion or pregnancy The precise nature of the immune substance is not always obvious

There have been several families in which consecutive babies have had neonatal thrombocytopenic purpura While the prognosis in the infant is usually good, with the restoration of a normal number of platelets within the first two or three weeks of life and usually not beyond three months, the course may not be benign When the pregnancy is associated with overt purpura, survival in the infant is jeopardized The early administration of vitamin K in moderate dosage is important because of the possibility of combined coagulation defects in addition to the thrombocytopenia If purpura is at all widespread and the platelets greatly reduced, steroid therapy is indicated Cortisone is administered, with approximately 40 mg given daily in divided doses for the first three or four days and the dose tapered off in the next two weeks, depending on the response Corticotropin (ACTH), approximately 20 mg daily in divided doses, given by injection, may be substituted for cortisone Hemorrhage may be controlled by these agents, with or without platelet response With bleeding or extensive purpura, transfusion of fresh blood is also necessary

TREATMENT OF METASTATIC BONE LESIONS

To the Editor —*Please provide information on the treatment of metastatic bone lesions, following removal of cancer of the breast This concerns a 52 year-old woman who has had extensive x-ray treatment of the lesions as well as sterilization She has also received hormone and cortisone therapy Surgery of the adrenals or hypophysis is not contemplated at this time Have any of the radioactive substances been used successfully for this type of lesion?*

M D , Illinois

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —A combination of intensive testosterone therapy and intravenously administered radioactive phosphorus (P^{32}) has been reported as being effective in some patients with widespread bony metastases from cancer of the breast While objective remission has been noted after such combination therapy, it is not certain whether this be due to the high doses of the testosterone, the P^{32}, or the combination A radiologist who is participating in an active isotope program should be consulted regarding this treatment

Answer —The earliest report of the use of radioisotopes for the treatment of metastatic bone lesions due to carcinoma of the breast was by Friedell and Storaasli (*Am J Roentgenol* 64 599, 1950) Radiophosphorus was given to 12 such patients in divided doses over a period ranging from 22 to 60 days The total dosage of P^{32} was from 12 to 18 mc The results with P^{32} alone were not impressive, although most of the patients experienced some relief of bone pain There is reason to believe that a great many individual cases have been treated in this way No large series has been reported, and possibly none has been accumulated, presumably owing, on the one hand, to the serious hematological complications and, on the other hand, to the fact that the results approximated those from intensive androgen therapy alone A recent development, which has not been reported in the literature, is a brief, intensive therapy with androgens combined with P^{32} In theory, the large androgen dose encourages a positive calcium (and therefore also positive phosphorus) balance, and the anabolic effect of androgen drives phosphorus into the tumor tissues Remissions induced in this way seem to be better than those resulting from other forms of therapy, although no long-term evaluations have appeared The suggestion to combine androgen and P^{32} originated with Dr J R Maxfield, of Dallas, Texas To this consultant s knowledge, no other isotope has been used with any significant effect in the treatment of this type of metastatic bone cancer

UNUSUAL SYNCOPAL ATTACKS

To the Editor —*A 41-year-old man has had four attacks of temporary loss of consciousness during the past four months These occur only when he is standing and urinating At other times he appears and feels perfectly well, but he cannot tell when these attacks may occur Two of the attacks were a month apart, but the last two have been within one week Physical examination is entirely negative His blood pressure is 118/70 mm Hg, his heart is normal, and urinalysis is normal The patient has neither a personal nor a family history of epilepsy After one of these attacks he feels all right except for the occasional bruise that he gets from falling Please comment on this case*

George J Treires, M D , Lock Haven, Pa

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —Syncopal attacks in the male, at no time other than when he is standing urinating is indeed somewhat unique As a matter of interest, a canvass was made of several internists, neurologists, and urologists, each of long experience and professorial rank, and none had knowledge or memory of such a circumstance

In this patient it is assumed that the negative history (except for the attacks) has included interrogation as to other vasomotor symptoms and also an evaluation of the psychic make-up of the individual In like manner the negative physical examination' assumes careful study of the ocular fundi and urogenital tract and a reasonably full neurological examination It seems that attention should be drawn in this case to such conditions as are more apt to cause syncope when an individual assumes a relatively motionless standing position rather than syncope induced by the act of standing from a sitting or other position In the former, fainting is possible from a variety of conditions that essentially cause fall in blood pressure Among these is the common vasodepressor syncope, or common faint This is due often to such things as sudden emotion, extreme anxiety, fear, or sight of blood Here, however, there is usually a prodromal period of weakness and sweating for a minute or two If this patient initially had a purely fortuitous fainting attack while urinating it should be comparatively simple to determine whether he has developed an anxiety neurosis concerning the act Probably of more importance is the ruling out of a vasodepressor carotid sinus reflex syncope This condition is rare and is caused by an oversensitive carotid sinus in the neck While often no cause for this overactive nerve plexus is found, rarely tumors and aneurysmal vessel dilatations pressing on the plexus are discovered Pressure over this area can cause drop in blood pressure and pulse, with syncope The trigger mechanism in setting off the attack can be as simple as the wearing of too *tight a collar, turning the head to one side, or raising* the face upward Many men wear collars that are entirely too snug It is not uncommon for some men, while urinating, to strike a pose in which the face, for some unknown reason, is directed well toward the ceiling Such factors alone or in combination, might well play a definite part in initiating a carotid sinus syncope Diagnosis of irritable carotid sinus is usually made by pressure or stroking over the carotid sinus areas while observing the pulse and blood pressure This procedure must be done with the greatest caution and with the patient sitting in bed as fainting can occur from the maneuver Treatment of the condition can be as simple as prescribing a loose collar and giving atropine several times daily In severe cases, surgical stripping of the nerve plexus may be indicated Allied somewhat to the last-described syndrome and causing a short or momentary cardiac standstill is reflex vagotonia Vagal inhibition of the heart may arise from the gastrointestinal tract, nasopharynx, eye, ear, respiratory tract, and the abovementioned carotid sinus plexus The urogenital tract has not been mentioned in discussions of this subject True Stokes-Adams syndrome, of course, may cause syncope, but the pulse is usually slow between attacks Thorough studies of the patient should include an electrocardiogram, which may give a lead to coronary pathology or unsuspected aortic valve pathology

Simple orthostatic hypotensive syncope seems unlikely in this patient, but blood-pressure readings when he assumes the supine, sitting, and standing positions should be made Syncope from such causes as cerebral circulatory or metabolic disturbances or neoplasm, while not strongly indicated from the data given, must be given serious consideration, especially if no lead is obtained from the foregoing Here a competent neurologist, with the aid of an encephalogram, can pass on such possibilities as tumor, epilepsy, and psychic and autonomic seizures Should further history taking bring out the slightest abnormality in the genitourinary system, urologic survey would be in order

Answer —These episodes are either seizures or syncope In spite of absence of history, psychomotor seizures must be considered, and an electroencephalogram should be the primary test If abnormal spiking is present, one must unavoidably conclude that epilepsy is at the root of the trouble, especially since injury (bruising) occurs With a normal tracing, the possibility of such a rare condition as a ball-valve tumor of the fourth ventricle cannot be overlooked A detailed history is of major importance in differentiating between the two types of loss of consciousness In syncope, the individual realizes what is going to happen and what has happened, whereas in epilepsy the attack is sudden and there is frequently a slight retrograde amnesia One should know the timing of these attacks and if they occur at night, especially just after the patient has risen from a recumbent position, since orthostatic hypotensive syncope occurs when the victim is standing motionless, especially after he has *been recumbent*

The carotid sinus syndrome with syncope would occur if there had been a gain of weight and the wearing of a tight collar, with straining (elevation of diaphragm) or turning or raising of the head A further procedure would be to fill the bladder with 500 cc of isotonic sodium chloride solution while the patient is recumbent, attach the blood pressure cuff to his arm, and determine the pressure as the patient stands and empties his bladder rapidly through the catheter, which has been left in place Decompression syncope or shock, although rarer than formerly believed, does occur with sensitive vasovagal systems Evidence from any witness to an attack would be of immense value in determining the type but not the mechanism Finally, it should be remembered that one of the auras preceding a psychomotor attack is the sensation of urinating, although it does not occur at that precise time

VITAMIN E THERAPY

To the Editor —*Is vitamin E therapy of any importance in any cardiac involvement, fertility, sperm activity, increased physical stamina, or deficiency disease?* William H Wright, M D , Elmont, N Y

Answer —There is no firm clinical basis for the use of vitamin E in the treatment of cardiac disease Nor is there any scientific evidence to prove that vitamin E is of value in the treatment of infertility in either sex There is no valid reason to assume that vitamin E administration might lead to increased vigor or be of benefit in the management of deficiency diseases

GLYCOSURIA WITH NORMAL BLOOD SUGAR LEVELS

To the Editor —*During a physical examination for a life insurance company, a marked glycosuria was noted in a 52-year-old man who had had no symptoms at all A glucose-tolerance test with 70 Gm of glucose revealed a fasting blood sugar level of 125 mg and, two and one-half hours after ingestion of the sugar, of 140 mg per 100 cc The fasting and* *two and one-half hour urine specimen again showed marked glycosuria Is there any special significance to blood values so close to normal in the presence of marked glycosuria?*

Maurice B Cohen, M D, Wildwood, N J

Answer —In interpreting the blood sugar values it would be helpful to know whether they were determined by the Folin-Wu or comparable method or by a procedure that determines only true glucose However, in either case the results are abnormal If they were determined by the Folin-Wu method, they indicate borderline or 'mild diabetes If they represent true glucose values, then definite diabetes is present It would be helpful to know what the peak value was during the glucose-tolerance test

In addition, the patient would appear to have a renal threshold for sugar lower than the average normal This occurs in diabetic as well as in nondiabetic individuals The lowered renal threshold represents a deviation from the average normal and would have no special significance It does, however, make somewhat more difficult the control of diabetes, since, if one strives for absolute freedom from glycosuria, hypoglycemia is encountered From a practical standpoint, from simultaneous determinations of the amount of sugar in urine and blood one gains an idea as to the level of the renal threshold and the amount of sugar in urine to be expected at a given level of blood sugar With this in mind, if insulin is being used, one adjusts the dose to allow glycosuria to that extent suggested by this experience

RESIDUAL EFFECTS OF LIGHTNING INJURY

To the Editor —*A man, 36 years of age, was struck by lightning in August, 1955 He lost consciousness and, upon regaining consciousness, found himself in the hospital and was there for 32 days He had burns on both heels and was in an oxygen tent for several days He was unable to move his legs and unable to turn over in bed his right arm was weaker than the left He was blinded for approximately three weeks, and then his vision gradually returned He had soreness of the scalp and was unable to comb his hair without discomfort He now has fatigue and falls asleep whenever he sits down Since the accident he has dreams of storms, thunder, and lightning He awakens, is frightened, has to turn on all the lights, and is afraid to go to bed unless someone else is present in the room with him He complains of marked pain at the level of the fourth thoracic vertebra He has also become very suspicious of his employers and thinks that he is being persecuted by them What permanent effect will a stroke of lightning, or electric shock, have upon personality and the above-named symptoms?*

M D, Michigan

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —Case reports of neurological deficit after lightning stroke abound in the literature, a brief review of which may be found in Wilson's encyclopedic "Neurology (Baltimore, William Wood and Company, 1940, chap 99) Microscopic changes have been demonstrated in the nervous system of persons dying of, or immediately subsequent to, being struck by lightning However, residual symptoms, such as have been described here, are usually classified as a "traumatic neurosis'

This man deserves a thorough neurological and psychiatric examination Such laboratory studies as electroencephalography and projective psychological testing should be utilized It would be impossible to make a prognosis without such examinations, neither could a realistic program of rehabilitation be outlined without them Neurologists particularly would recognize what may be the syndrome of narcolepsy within the symptomatic galaxy (see Langworthy and Betz *Psychosom Med* 6 211, 1944)

Answer —A person struck by lightning receives an electric discharge of some millions of volts, which act for a small fraction of a second Acute changes occur in both the central and the peripheral nervous systems

In patients who survive, the residual lesions in the central nervous system are more probably due to damage of blood vessels and cerebral anoxemia secondary to temporary failure of respiration Petechial and gross hemorrhages have been observed in the brain and meninges Nerve-cell alterations and degeneration of the myelin sheath and axons can occur

Distinct clinical residuals may result from such electric shock, and sequelae may last for months or be permanent Such injuries may involve the spinal cord and brain, with motor residuals, including flaccid paralysis, sensory loss, papilledema, optic atrophy, and mental changes Neurotic symptoms frequently follow such an accident and are most difficult to differentiate from true organic residuals Emotional symptoms include insomnia, forgetfulness, fatigue, irritability, and anxiety The presence of persecution and paranoid ideas may be due to a basic personality disturbance activated by the electric trauma, rather than an organic lesion

INTRAVENOUS CHOLANGIOGRAPHY

To the Editor —*A 46-year-old man has had a series of three oral cholecystograms because of epigastric discomfort The first two series showed nonfunction, and the third series showed normal function Three days later he developed clinical jaundice, with an elevated serum alkaline phosphatase level and normal cephalin flocculation and thymol turbidity values The initial icteric index was 22 6, and this decreased slowly to 14 in five days The patient had received 10 mg of chlorpromazine (Thorazine) four times a day for four days six weeks prior to admission An intravenous cholangiogram was requested and refused by the radiologist on the grounds that the dye might increase the parenchymal damage Please provide an opinion on the following questions 1 Is the dye used in intravenous cholangiography damaging to liver cells, to normal cells, in partial obstruction of bile outflow, in hepatitis, and in chlorpromazine-induced jaundice? 2 Is a raised icteric index in the presence of a functioning extra-*

biliary system a contraindication to intravenous cholangiography? 3 Is intravenous cholangiography helpful in diagnosis of partial obstruction of the common duct? The patient s stools have remained normal in color The gastrointestinal series shows a normal duodenal loop There has been no weight loss or anorexia, and patient is now asymptomatic

Robert E Sandlin, M D , Antioch, Calif

ANSWER —1 There is no evidence that sodium iodipamide (Cholografin) or methylglucamine iodipamide (high potency Cholografin) are injurious to normal or damaged liver cells 2 An elevated icteric index is not considered a contraindication to intravenous cholangiography If the dye is not excreted through the biliary tract either because of hepatocellular impairment or extrahepatic or intrahepatic bile-duct obstruction, the dye is readily excreted by the kidneys A combination of marked renal and hepatic impairment can be considered a contraindication to intravenous cholangiography Intravenous cholangiography is generally not attempted in the presence of marked icterus because ductal visualization is rarely accomplished under such circumstances However, visualization of extrahepatic ducts has been reported with sodium iodipamide in a patient with a serum bilirubin level of 4 8 mg per 100 cc (Wise and O Brien *J A M A* 160 819 827 [March 10] 1956), and in another patient with a serum bilirubin level of 7 5 mg per 100 cc the ducts were visualized with methylglucamine iodipamide (Berk and others *Am J M Sc* 231 289, 1956) 3 If the obstruction of the common duct is accompanied by marked icterus, the probability of visualizing the extrahepatic duct by intravenous cholangiography is small However, as stated above, in mild to moderate hyperbilirubenemia the ducts are occasionally visualized, and in such instances this would be diagnostically helpful The ideal patient for intravenous cholangiography is one with disease of the extrahepatic ducts without icterus From the data given, a diagnosis of intrahepatic cholangitis due to chlorpromazine is most likely

SEQUELAE OF MENINGOCOCCIC MENINGITIS

To THE EDITOR —*Over 10 years have elapsed since many military personnel were successfully treated for meningococcic meningitis It was speculated, at the time of treatment, that possible neurological sequelae might develop in later years as a result of this usually fatal disease Are there any data available to confirm or deny this early speculation?*

Charles C Stehly, M D , Los Angeles

ANSWER —In 1953, a study was made of late complications in 178 cases of meningococcic meningitis that occurred during the period 1935-1945 Of these patients, 49 5% reported postrecovery symptoms of one type or another The remaining 50 5% denied any aftereffects upon recovery

Headache was the most frequent complication (32%), and, of these headaches, 77 7% were localized, most frequently to the occipital area Hearing loss or impairment occurred in 12 3% of the patients, of whom 57% had bilateral involvement, the degree of involvement differed in the two ears in about two-thirds of the patients Only 14% of these patients were benefited by hearing aids Fifty per cent of the patients reported improvement in hearing in time from their original impairment Other neurological sequelae were fainting spells (3 9%) and convulsions, which occurred in one patient during hot weather Non-neurological residuals were joint pain, muscle pain, and muscle twitches, these make up the remaining complications Two-thirds of the patients with sequelae reported an exaggeration of symptoms under certain circumstances, such as changes in weather, altered work conditions, exercising, and drinking of large quantities of salt-free water

CALCIUM AND PHOSPHORUS IN PREGNANCY

To THE EDITOR —*My attention was called recently to the query in* THE JOURNAL *for July 14, 1956, page 1117, regarding calcium and phosphorus in pregnancy The question of the extent of mineral intake and its balance in pregnancy is of interest to the dentist because of the fact that a notable amount of calcification of the deciduous teeth takes place during intrauterine life Clinical evidence has shown that these teeth vary in structural soundness and susceptibility to caries from child to child I base this comment on observations made at the Guggenheim Dental Clinic in New York City, of which I was director for many years*

It seems logical to assume that the best chance of the child s having sound deciduous teeth is when the optimal amounts and proportions of these minerals, as well as other elements, are provided for the pregnant woman

The answer states that it seems advisable not to administer phosphorus-free calcium, since either calcium or phosphorus, when fed in excess, causes an increased excretion of the other element The consultant then goes on to state that the pregnant woman should have a daily intake of 1 5 Gm of calcium and approximately as much phosphorus The proportion of these elements in milk (1 15 Gm of calcium and 0 908 Gm of phosphorus) undoubtedly is excellent and apparently should be maintained in the diet as a whole However, this proportion is upset when bread and cereals are added to the diet in any considerable amount, as often happens These foods make their own valuable contribution to the daily menu, but they do present a great preponderance of phosphorus over calcium, thus tending to create the danger mentioned

In view of this fact, it would seem to me that calcium supplementation of the diet might well consist of administration of calcium salts such as *the gluconate or lactate, in reason, without fear that the diet as a whole will be too low in phosphorus I would appreciate your comment on this*

John Oppie McCall, D D S
944 Park Ave
New York

The above comment was referred to the consultant who answered the original query, and his reply follows —Ed

To the Editor —*The correspondent writing the letter is correct when he states that if grain products such as bread and cereals make up a significant part of the diet the amount of phosphorus they contain would have a demonstrable effect on the calcium-phosphorus ratio However, it should be pointed out that the phosphorus present in grains is largely in the form of phytic acid Calcium phytate is highly insoluble, so the ingestion of phytic acid usually results in the loss of its own phosphorus together with calcium supplied by other foods, except as vitamin D present makes some of the phytic acid phosphorus available Therefore, the correspondent is right when he claims that the phosphorus-calcium ratio would be altered, but it would not be because of an excess of phosphorus but because the form of the phosphorus acts to make both it and some of the dietary calcium unavailable In those cases where grains do make up a large part of the diet the use of some calcium salt might be desirable In England, calcium carbonate is added to the flour in sufficient quantities to compensate for the phytic acid content*

BIOLOGIC FALSE-POSITIVE SEROLOGIC REACTIONS

To the Editor —*In* The Journal *for Feb 9, 1957, page 516, there appears a query concerning biologic false-positive serologic reactions The inquiring physician is interested in the incidence of this phenomenon and wonders if the frequently quoted' figure, '40%," is correct Neither of the two consultants seemed to make clear the correct answer to the question concerning 40%' Since I am responsible for the data in question, it would be desirable for me to amplify the answer to the query I have said that, of positive serologic tests (with standard lipid antigens) routinely discovered (e g , in premarital, preemployment, prenatal, pretransfusion, and other such routine tests) in persons who give no history of infection with syphilis and of no reasonable exposure to it and who present no physical evidence of the infection, about 40% of these seropositive reactors do not have syphilis but are instead biologic false-positive reactors This statement is limited to white persons of the upper educational and socioeconomic level drawn from the population of the northern United States*

The identification of such persons as biologic false-positive reactors is accomplishable by means of serologic testing with any one of the variety of techniques utilizing antigens prepared from Treponema pallidum The mere identification of the patient as a biologic false-positive reactor does not, however, differentiate between the benign acute biologic false-positive reaction, which has no significance for the patient's subsequent health, and the chronic biologic false-positive reaction, which is of major significance to his health

J E Moore, M D
The Johns Hopkins Hospital
Baltimore 5

CHROMHIDROSIS

To the Editor —*Concerning the query (*J A M A **163** *703 [Feb 23] 1957) on chromhidrosis, it is suggested that the physician test the patient's urine with dilute ferric chloride solution to rule out alkaptonuria The gray discoloring of clothing is* common to this disease

R de R Barondes, M D
1031 S Broadway
Los Angeles 15

To the Editor —*In the Query and Minor Note in* The Journal, *Feb 23, 1957, page 703, entitled 'Chromhidrosis," the consultant did not mention two conditions that may rarely be associated with this symptom A patient with acute intermittent porphyria presented the interesting story that his clothing and bedclothes were stained brown for several years preceding the onset of his abdominal pains that led to the diagnosis A patient having ochronosis with alkaptonuria observed that his sweat had discolored his clothing as long as he could remember The search for etiological agents of chromhidrosis is simplified if the patient should have either of these conditions*

Frank L Iber, M D
The Johns Hopkins Hospital
Baltimore

The above comments were referred to the consultant who answered the original query, and his reply follows —Ed

To the Editor —*The available books on dermatology do not list alkaptonuria or porphyria as causes of chromhidrosis All these named entities are comparatively unusual Unless the sweat itself reacted to tests for porphyria or alkaptonuria, these reports would not establish a conclusive relationship between the discolored sweat and the entities under consideration After all, the patient could have ochronosis plus chromhidrosis due to other causes such as the ingestion of a chromogenic drug However, by anology with the excretion of these substances in the urine by patients with porphyria and ochronosis, it seems likely that these metabolic disturbances could lead to discolored perspiration A bluish sweat due to the presence of iron salts may occur in hemochromatosis The observations of the correspondents are of great interest and increase our knowledge of this poorly understood but, fortunately, rare condition*

NATIONAL LIBRARY OF MEDICINE BUILDING IN BETHESDA

A new building to house the National Library of Medicine, created last year out of the Armed Forces Medical Library, will be constructed at Bethesda, Md , on the grounds of the U S National Institutes of Health

Bethesda, a Washington, D C , suburb, was selected by the library s regents at their second meeting Under the law creating the library, the surgeon general of the Public Health Service was authorized to select the site in accordance with the direction of the board Ten of the 17 members of the board are appointed by the President, with the remainder consisting of federal officials serving ex officio The chairman is Dr Worth B Daniels of Georgetown University Medical School, Lieut Col Frank B Rogers, who was head of the Armed Forces Medical Library, is director of the National Medical Library and secretary of the board of regents

Late in the last session of Congress, before the act creating the library had been passed, Illinois members of Congress and a group of officials and medical leaders from Chicago put on a campaign to win the building for that city Up to that time it had been assumed it would be located in the Washington area, which was designated by one of the bills under consideration

When the bill was enacted, however, the controversy was bypassed by leaving the selection up to the board

Congress last year authorized the spending of money for surveys and site selection, but did not appropriate money for construction, nor is construction money contained in the Public Health Service budget, which has passed the House and now is before the Senate Appropriations Committee Now that a site has been chosen, there is a possibility that the Senate committee will add construction money to the PHS budget

'In arriving at its decision,' an announcement from the PHS says, the board considered both area and specific site Since government agencies in the Washington area are among the major users of the library s services, the board concluded that any move outside this area would lead to costly duplication of services In addition, the board agreed that moving the library s extensive collection of books and other materials would entail an expense that was not justified'

According to the PHS, the Association of American Medical Colleges and the Association of American Dental Schools both favored the Washington area, whose advantages, the board decided, "far outweighed those of other locations'

The Bethesda site was chosen over others in the Washington area because of a number of factors, including proximity to two large medical centers (NIH Clinical Center and Bethesda Navy Hospital), availability of sufficient land for future expansion, a good network of transportation, suitable terrain, supporting services and facilities, and parking room

CHAMBER HEARS OF BUDGET ECONOMY HOPE

Leaders in both parties believe the total federal budget can be cut by at least 3 billion dollars despite administration insistence that the scale of spending is necessary and sound Predictions of reductions in the budget starting July 1 were made at the 45th annual meeting of the U S Chamber of Commerce, held in Washington Senator Knowland (R , Calif) told the delegates he believed a 3-billion-dollar cut could be made in the 71 8-billion-dollar total Senator Mansfield (D , Mont) agreed

Senator Byrd (D , Va) went much farther than any other economy advocate, telling the chamber that the budget should be cut back to 1955 spending, which would mean a reduction of 7 2 billion dollars If that is done, he said, Congress could cut taxes by 6 3 billion dollars Senator Byrd described the administration s proposed budget as 'the most irresponsible budget submitted in my day

Vice-president Nixon spoke on behalf of the administration, reminding the businessmen that about 60% of the budget reflects spending for national security He also reminded them that the President has given them the biggest tax cut in history and pressing for new savings

Senator Knowland forecast that federal construction aid to schools would not pass, but he made no prediction about bills pending in House and Senate for construction grants for medical schools Legislation probably will be approved, he added, to regulate union and other pension and welfare funds Commenting on proposals for a four-year program for general school construction aid, the California senator said "My practical knowledge of Washington leads me to the conclusion that nothing terminates in four years And I have never seen the federal government contribute money without wanting to exercise control

SECRETARY FOLSOM'S ADVICE TO BUSINESSMEN

Secretary Folsom believes businessmen should take the same lively interest in programs dealing with health, education, and economic security as they do in those involving taxes' If the business community wants federal activities in these fields held to a minimum, he told a business group then businessmen should lead and support efforts in these fields by private enterprise, voluntary organizations, and state and local governments

He outlined his views in a talk before the Midwest Business Conference of Harvard Business School 'The question is not whether genuine needs will be met,' Mr Folsom said, "but how if the needs are not met in one way, sooner or later the people will see that they are met in another'

From the Washington Office of the American Medical Association

The head of HEW asked the business leaders to what extent their firms have provided private pension plans for old age, controls for water and air pollution from industrial wastes, safety programs, and support to training and education of people with technical skills

Urging preventive programs in the welfare fields, he cited two items in the proposed 1958 budget (*a*) 2 million dollars for research on why people become dependent on public welfare and (*b*) $2,500,000 for training more professional workers to help persons on assistance build financial independence Mr Folsom also noted the heart research studies and the rehabilitation program as examples of constructive welfare In the 1958 budget, he noted 1 5 billion dollars, or 65%, is assigned to public assistance to the needy, aged, blind and disabled, and to dependent children

NATIONAL HEALTH SURVEY UNDER WAY

The National Health Survey, the most ambitious ever undertaken, has begun It was launched May 6 with 106 professional interviewers ringing doorbells in sample areas of the 48 states The survey is a continuing thing, and each month a different group of householders will be visited

Information being collected by the Public Health Service includes statistics on the number, age, sex, and other personal characteristics of people suffering from various diseases, injuries, or handicapping conditions Also sought are length of time these persons have been prevented from carrying on their usual occupations or activities, and the volume of medical and dental care received

Statistics will be compiled both for the nation as a whole and for each of 11 geographical regions Data from the regions will be grouped by large metropolitan areas, other urban areas, and rural areas Additionally, statistics will be compiled for eight cities having more than 2 million population—New York, Chicago, Los Angeles Philadelphia, Detroit, San Francisco, Boston, and Pittsburgh

Surgeon General Burney points out "This survey is a most important step in the health field The information it will provide is long overdue For many years, physicians, research workers, insurance companies, hospital personnel and others concerned with health have been in urgent need of facts on the health of the general population"

Actual sampling is being done by Bureau of the Census The survey was authorized by the last Congress

SALK VACCINE SUPPLY CONTINUES TO INCREASE

Latest statistics from the Public Health Service show 8,200,000 cc of Salk vaccine on hand for the week ending April 19, compared with 6,300,000 the week before and 4,700,000 the first week in April

Of the April 19 inventory, 4,500,000 cc was in the hands of manufacturers and 3,700,000 in warehouses, pharmacies, health departments, and doctors' offices

Production of 12,283,785 cc during April alone compares with just under 15 million produced in the three previous months of this year During the week of April 26 a total of 3,918,240 cc of vaccine was released by the PHS

REPORT ON SAFETY VALUE OF AUTO BELTS

Two auto researchers report that use of the safety belt reduces human injuries in auto accidents by 60% The two are John O Moore, director of automotive crash injury research at Cornell University, and Edward R Dye, head of safety design and development at Cornell's aeronautical laboratory They presented their views before a House subcommittee that is considering federal legislation to promote auto safety

Mr Moore said that, of more than 12,000 auto accidents screened last year, 81 cars where safety belts were used were selected for matching against similar cars in similar accidents where the belts were not used The finding was that passengers or drivers protected by safety belts suffer 60% less injury The safety belts are not a panacea, Mr Moore said, but they 'definitely are a factor in reducing injuries'

Mr Dye admitted that a form of harness is more effective than the lap belt, but that people are reluctant to be strapped in that way and that the harness cost (about $500 per car) also retards its general adoption He said no one wearing a lap belt is ever injured by the belt itself

Answering some published criticism of the belt, the witnesses said these opposition claims were based on tests with cars carrying dummies running up against solid obstacles, a form of accident that accounts for only 16% of recorded auto mishaps

The Cornell research project, sponsored by the university's medical college, has the cooperation of 14 states and receives support from Defense Department, Public Health Service, state agencies, and the automotive industry A number of other states have indicated they wish to participate

It is not anticipated that the committee will take action this session Hearings may be continued after Congress adjourns, with some possibility that the investigation will look into the relationship between tranquilizing drugs and accidents

MENTAL HEALTH WEEK

During Mental Health Week, Vice-president Nixon and Senator Smathers (D, Fla) joined in launching a nationwide fund-raising drive for research on and prevention of mental illness Senator Smathers, sponsor of Mental Health Week resolution in Congress, called this the 'No 1 illness in the United States today'

As the observance began, the Red Cross noted its volunteers spent 484,000 hours in civilian mental institutions assisting in the rehabilitation of patients in 1956, a substantial increase over the previous year The increase is due to the larger number of local chapters instituting programs of volunteer service with local hospitals

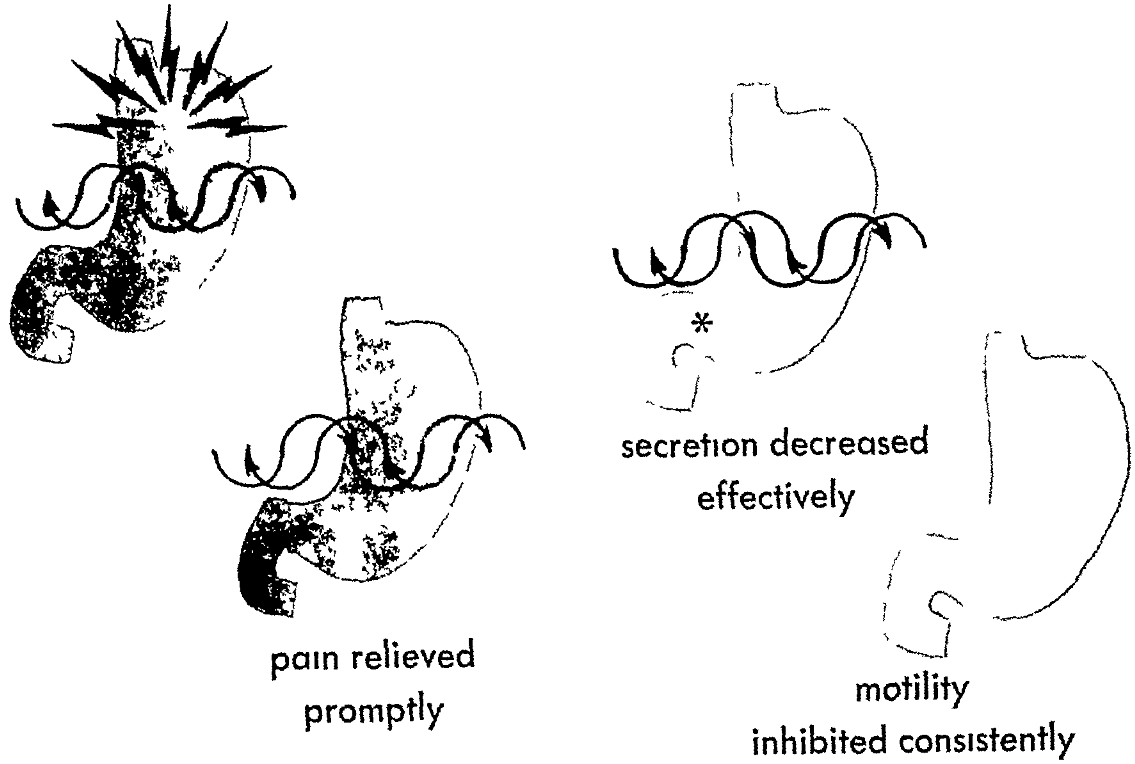
Mr Nixon urged everyone to make contributions "which will help these people (through such programs as the Red Cross's) in our communities"

MISCELLANY

Russia officially has returned to the World Health Organization after an absence of eight years Accusing WHO of anticommunist policies, all Soviet-bloc countries walked out in 1949 Albania, Bulgaria, and Poland recently resumed membership, and Czechoslovakia, Hungary, Rumania, Ukraine and White Russia are expected back soon

CONFIRMED THERAPEUTIC UTILITY

Pro-Banthine®...
A Primary Drug in Peptic Ulcer



Among the many clinical indications for Pro-Banthine (brand of propantheline bromide), peptic ulcer is foremost Pro-Banthine has been shown repeatedly to be a singularly valuable agent when used in conjunction with diet, antacids, sedation and psychotherapy as required Lichstein and his associates[1] report that Pro-Banthine "proved almost invariably effective in the relief of ulcer pain, in depressing gastric secretory volume and in inhibiting gastrointestinal motility The incidence of side effects was minimal "

The therapeutic utility and effectiveness of Pro-Banthine in the treatment of peptic ulcer are repeatedly confirmed in the medical literature Dosage One tablet with each meal and two tablets at bedtime

orally with

NOVAHISTINE®

In the management of seasonal allergies and the common cold, Novahistine works better than antihistamines alone The distinct additive action of a vasoconstrictor with an antihistaminic drug *combats allergic reactions* more efficiently provides marked nasal decongestion and inhibits excessive irritant secretions Novahistine eliminates patient misuse of nose drops, sprays and inhalants is not likely to produce rebound congestion nor make the patient "jittery "

Each Novahistine Tablet or teaspoonful of Elixir provides 5 0 mg of phenylephrine HCl and 12 5 mg of prophenpyridamine maleate For patients who need greater vasoconstriction, Novahistine *Fortis* Capsules contain twice the amount of phenylephrine

I Was Afraid to Be Normal, by Frances Warfield
The story of the new and terrible struggle that begins for the author, partially deaf since childhood, when at last she learns that she can be completely cured

Queen Juliana's Story by Geoffrey Bocca
This article tells of how faith healer Greet Hofmans influenced the Dutch royal household when she was retained to help Queen Juliana's daughter regain her sight Miss Hofmans eventually was dismissed at the suggestion of the Queen's advisers

Fortune, May, 1957
The Tranquilizer Question, by Francis Bello
In just three years tranquilizers have broken all growth records of the drug industry But no one is yet certain what happens to people when they take these pills—or if they should'

Reader's Digest, May, 1957
New Weapons Against Heart Disease, by Francis and Katherine Drake
The article states that improved methods of detection and treatment, plus a sensible diet are reducing coronary attacks

Still Voice by Eloise O'Mara
A wife's poignant story of how her husband learned to speak again after cancer had taken his voice

Redbook, May, 1957
How to Stay Healthy While Traveling, by Wallace Croatman
The author tells how to increase your family's chances of staying healthy while away this summer—or, at the very least, to prepare for emergencies

Good Housekeeping, May, 1957
Hypnosis, by Judith Tarcher and Philippe Halsman
According to the article, hypnosis is now called mental anesthesia and is being used as an aid in every form of surgery

Saturday Evening Post, May 4, 1957
That Creeping Menace Called Smog by Leigh White
Pollution of the air hovers over most of our cities, costs us billions in health and property damage and sometimes kills

Saturday Evening Post, May 11, 1957
The Burma Surgeon Carries On
This story is a profile on the famed Burma surgeon Dr Gordon Seagrave

Seventeen, May, 1957
Adolescence an interview with Dr J Roswell Gallagher
The chief of the adolescent unit of the Boston Children's Hospital explains the changes that an adolescent girl's body undergoes and recommends several ways to alleviate two of the most usual problems—cramps and acne

Better Homes and Gardens, May, 1957
Bomb Dust Radiation! by James Poling
The work of the Atomic Energy Commission's health and safety laboratory—the trouble-shooting branch of the AEC's division of biology and medicine—is the subject of this article

Consumer's Report, May, 1957
When Your Child Goes to the Hospital
Advice on what parents can do to help a child overcome fear and adjust to the hospital environment is given in this article

Varicose Veins
The report says the exact cause of varicose veins is unknown and the several varieties require different handling It explains methods of treatment and suggests certain measures of value in delaying the enlargement of the veins and in preventing major complications of varicosity

The Age of Tablet-Rioty

What happened to the pearl or pill
To cure the many who are ill?
Our fathers were satisfied with capsules
We have to take Spansules
Other millions prefer colored Kapseals
Except those with a delicate tummy who have to take Enseals
You may get relief from a Capsulette, Caplet, Emplet, or Tymcap
Or, maybe you prefer a Timesule, Trisule, Tempule, or Duracap
For those who like neither tablet nor capsule
There is available now the Tabule
When you need action prolonged and extended
You can use a Duratab, Spacetab, Extentab, or Repeatab with an effectiveness previously never comprehended
They will give you delayed, repeated, or sustained surcease
Whereas others promise you sequential release
For a tablet to hold but a single ingredient
Would not be expedient
We need a tablet that is complex
So you have the Prestab, the Encore, the Strand, Rotocote, and Duplex
And Heaven forbid
We should chew it
We would have to bite through the outer core, the inner core, and the center
And who would dare to venture?
For a tablet to be coated enteric
It now has to be engestic coated or Duenteric
But alas, if you are still under par
Maybe an Ovoid, a Suprette, Homagenette, or Unicette will bring you back to the bar
If your kiddies need medication and you don't want them to spill it
You can tempt them with an Infatab, Tasticap, Softab, Dulcet, Candisphere, Medilet, or Pillette
And as for the lozenge, used by the old lady with the lorgnette,
She can now soothe her throat with either a Sucret or a Pharynget
Don't let's call this the age of anxiety
But rather name it the age of tablet-rioty,
And if neither an ataraxic, calmative, tranquilizer, mental clarifier, or psychosedative brings you back to sanity
You can always disappear
With a Sphere.—Paul de Haen

The Pathology of Boredom

Aviators sometimes suffer hallucinations during long monotonous flights. The phenomenon is illuminated by a general examination of the effect of prolonged exposure to a monotonous environment. The aim of the project was to obtain basic information on how human beings would react in situations where nothing at all was happening.

The subjects were male college students paid $20 a day to participate. They lay on a comfortable bed in a lighted cubicle 24 hours a day for as long as they cared to stay, with time out only for meals (which they usually ate sitting on the edge of the bed) and going to the toilet. They wore translucent plastic visors which transmitted diffuse light but prevented pattern vision. Cotton gloves and cardboard cuffs extending beyond the fingertips restricted perception by touch. Their auditory perception was limited by a U-shaped foam rubber pillow on which their heads lay and by a continuous hum of air conditioning equipment which masked small sounds.

We began with a preliminary run in which we merely observed the subjects' behavior and interviewed them afterward. Most of these subjects had planned to think about their work, some intended to review their studies, some to plan term papers, and one thought he would organize a lecture he had to deliver. Nearly all of them reported that the most striking thing about the experience was that they were unable to think clearly about anything for any length of time and that their thought processes seemed to be affected in other ways. We therefore decided that the first thing to do was to test effects on mental performance. We used three main methods of investigating this. One was a battery of oral tests involving simple arithmetic, anagrams, word association and so on. This battery was given before the experiment, at 12, 24 and 48 hours during the isolation and finally three days afterward. Another battery of tests, given two days before and immediately after the isolation period, included copying a design with blocks, speed of copying a prose paragraph, substituting symbols for numbers, picking out what was odd in each of a series of pictures (for instance, one picture showed a man in a canoe using a broom instead of a paddle) and recognizing patterns embedded in a complex background. The third test used the recording of a talk arguing for the reality of ghosts, poltergeists and other supernatural phenomena. It was played to each subject during his isolation and after he had emerged.

On almost every test the subjects' performance was impaired by their isolation in the monotonous environment (and was poorer than that of a control group of students). The isolation experience also tended to make the subjects susceptible to the argument for the existence of supernatural phenomena. Some of them reported that for several days after the experiment they were afraid that they were going to see ghosts. . . . The content of their thought gradually changed. At first they tended to think about their studies, about the experiment, about their personal problems. After a while they began to reminisce about past incidents. . . . To pass the time some tried to remember in detail a motion picture they had seen; others thought of travelling from one familiar place to another and would try to imagine all the events of the journey; some counted numbers steadily into thousands. . . . Eventually some subjects reached a state in which it took too much effort to concentrate, and they became "content to let the mind drift." . . . The subjects became markedly irritable as time went on and often expressed their irritation. Yet they also had spells when they were easily amused.

They also said that they seemed to lose their "sense of perspective" while in the cubicle, and some subjects mentioned that at times they felt that the experimenters were against them, and were trying to make things exceptionally tough for them. The subjects reported something else to which we at first paid no particular attention but which was to emerge as the most striking result of the experiments. Many of them, after long isolation, began to see images. One man repeatedly saw a vision of a rock shaded by a tree; another kept on seeing pictures of babies and could not get rid of them. Several subjects seemed to be "having dreams" while they were awake. Not until one of the experimenters himself went through the isolation experience for a long period did we realize the power and strangeness of the phenomenon. His report, and a review of the literature on other experiments in monotony, made clear that the experimental situation induced hallucinations.—W. Heron, The Pathology of Boredom, *Scientific American* January, 1957

THE CHANGING DISTRIBUTION OF HELMINTHIC DISEASES IN THE UNITED STATES

Carroll L Birch, M D
and
Basil P Anast, M D , Chicago

• *Trichinosis exemplifies the importance of helminthic diseases in this country the number of cases of trichinosis in the United States exceeds that in any other country in the world Tropical diseases are brought to the United States by people returning or immigrating from other countries, an example is American trypanosomiasis, the first case of which in the United States was reported in Texas in 1955 Schistosoma mansoni and Wuchereria bancrofti are being brought to the mainland of the United States from the West Indies, especially from Puerto Rico Many cases of schistosomiasis have been reported since 1950, especially in northern cities such as New York and Chicago Parasites endemic in one area within the United States are carried occasionally into other areas, as is illustrated by an outbreak of infestation with Strongyloides in a school in Illinois after the arrival of children from New Mexico The authors give many other examples, and the fact that these problems are not peculiar to the United States is illustrated by recent migrations of Jamaicans to England, Indonesians to Holland, and Algerians to France Two million American tourists have visited foreign countries since World War II Increased attention to the principles of sanitation and hygiene is urgently needed in order to reduce the disability now caused by parasites and to prevent parasites from establishing themselves in new areas*

Parasitism as a way of life is present throughout the vegetable and animal kingdoms Parasites have few racial preferences or prejudices, they seem to be attracted to man by more subtle attributes There is evidence that parasites have plagued the human race since the dawn of history for the much toward social betterment is parasite ridden

The symptoms produced by parasites vary from none at all to fulminating, resulting in death This variability depends on many factors usually summed up by the phrase "virulence of the organism and resistance of the individual" which conceals much lack of knowledge

A truly successful parasite develops a state of equilibrium with its host and does it no harm for the life of the host is essential for the life of the parasite Perfect parasitism produces no pathology When the parasites become too numerous this balance is disturbed and disease is the result Also in a community where the resistance of the individuals is low or the diet poor, parasites become a great physical and economic burden on the people The human suffering caused by Plasmodium malariae Entamoeba histolytica and Ancylostoma duodenale (hookworm) and other round worms and flukes, especially schistosomes, can not be estimated

There is reason to suspect that some parasitic and tropical diseases are on the increase Toxoplasmosis has spread in recent years Isospora belli made its initial appearance in Florida in 1955 Capillaria hepatica in a living person in Maryland was diagnosed for the first time in 1954, and McInown reported a case in New Orleans

American trypanosomiasis (Chagas' disease) is one of the more important public health problems in Guatemala and other Central and South American countries During 1955 the first patient with this disease in the United States was reported in Texas[1]

Dreaded yellow fever occurred in most of the Central American countries between 1949 and 1954 In 1948 a wave of jungle yellow fever moved along the Atlantic rain forest from Panama It reached Costa Rica in 1951 Then it reentered West Panama and moved into Nicaragua Romero and Trejos[2] report the mortality rate in children under 12 years of age with yellow fever to be 6 2%, while in adults it is 27 4%

From the University of Illinois College of Medicine

Read before the Section on Pathology and Physiology at the 105th Annual Meeting of the American Medical Association Chicago, June 13, 1956

The number of cases of trichinosis in the United States exceeds that in any other country in the world Relapsing fever exists in Texas One hundred cases were confirmed by finding the spirochetes in the blood The vector Ornithodoros turicata, was studied in 44 counties Specimens from 36 counties harbored spirochetes[3] Radke and others[4] studied a single stool specimen from each of 4,438 food handlers About 10% harbored pathogenic agents

Baar[5] has reported on a new disease, which he calls "interstitial plasmacellular pneumonia' It is caused by a protozoan, Pneumocystis carinii, and has appeared in Europe It produces honeycombed areas in the lung Thus far, no cases have been reported in the United States Ritchie,[6] in his parasitological study of the Far East, examined 2,211 persons, 79% showed helminths and 48% protozoa Corrêa's[7] examination of 55,764 children between 7 and 14 years of age in Brazil revealed that 70 44% harbored helminths In Santiago, the examination of 3,902 pupils indicated that 25 73% carried Entamoeba histolytica, 15 73% Giardia lamblia, 27 37% Ascaris lumbricoides, 15 76% Hymenolepis nana, and 36 48% Enterobius vermicularis

Dr Norman B McCullough, a clinical chief at Bethesda, Md , said, 'What is left in the infectious grab bag is still formidable Most virus diseases are mysterious and unsolved Antibiotics, which knock out bacteria, are powerless against them Hepatitis, the common cold, fungus and parasitic diseases are still uncommonly difficult problems "

Vigorous attacks should be made against these remaining enemies which continue in their cycles of destruction The United States and other scientifically advanced and sanitation-conscious countries have the necessary laboratory facilities, but medical men seldom think of examining for parasites In the underdeveloped countries they think of parasites but often have few laboratory facilities Diagnosis of most parasitic diseases can be made by simple laboratory procedures, performed by experienced examiners

The names of even the commonest parasites are unfamiliar to many practitioners A clear picture of the present parasitological problems may be of interest and the subject found no less worthy of attention than the other branches of medicine At present, parasitism presents a serious social situation in the United States and the rest of the world The concept and teaching of parasitology is constantly changing During wars it is emphasized, during interwar periods it is forgotten When World War II ended, so did the fight against parasites

Parasitology is not concerned so much with climate as with underdeveloped and overpopulated areas any place in the world where sanitation measures have not been applied Such regions are inhabited by about three-fourths of the peoples of the earth By sheer weight of numbers the subject becomes important The presence or absence of parasites is determined more by the sanitary facilities of a country and the hygiene of its citizens than by the climate Personal cleanliness, that is, body bathing, has little influence on these conditions Dr Asa C Chandler[8] is of the opinion that exotic and parasitic diseases are the result of substandard ways of life in bad environmental conditions He says, "Even if we ignore the moral responsibility can we afford to allow it to pass unnoticed from an economic standpoint?'

Reasons for Increase in Parasites in Northern United States

Parasites have become more numerous in the northern cities of the United States for several reasons

Migration from Endemic Areas —The entrance of large numbers of citizens into northern cities, begun a number of years ago, is now in progress and will probably continue for years to come Recently many persons, chiefly Negro, but also white, have migrated from the southern states They have exchanged the cabin in the South for the tenement in the North Roi Ottley, in one of a series of articles in the Chicago *Tribune*, stated that 2,500 Negroes arrive in Chicago each month They bring with them their cultural patterns, their eating habits and, as the South has more parasites than the North, an unknown number of parasites As stated before, parasites have no race preference, but there is some evidence that Negroes have greater immunity than members of other races to certain strains of vivax malaria and perhaps to some other parasites Our southern states have always had a higher index of parasites than the northern states Young[9] reports that an examination of a single specimen of stool from each of 2,908 school children showed parasites in 33 2%

Citizens from Puerto Rico have been reaching the mainland of the United States in large numbers According to the United States census of populations, there were 1,513 Puerto Ricans in the United States in 1910, in 1930 the number was 52,744, and in 1950 it had increased to 226,110 Many others have arrived during the past few years There were 187,500 Puerto Ricans in New York City in 1950 and 700,000 in 1956 In 1950, Chicago housed 1,700 According to a recent survey made by Saul D Alinsky, there are 22,000 persons from Puerto Rico in Chicago According to John Justin Smith's report in the Chicago *Daily News*, May 9, 1956, "Thousands more will probably come in the next few years " They are arriving at the rate of about 400 per month

Citizens from Puerto Rico and immigrants from the West Indies and South America harbor many parasites It must be remembered that the southern Negro is a full-fledged citizen and has been for many generations Puerto Ricans, too, are full citizens The United States has controlled the island of Puerto Rico since 1898 Progress in sanitation has been made Yellow fever has been eliminated and malaria is almost a disease of the past, but the protozoa, round worms, and flukes still flourish These citizens from the South and from our island possessions usually settle in the poorer sections of the northern cities and in overcrowded areas For their sakes and that of the community they should be treated for parasites Freedom from parasites will lead to improved physical condition and to greater efficiency among students and workers

Travel and Work in Endemic Areas.—Visitors and workers frequently return from endemic areas with fevers and gastrointestinal upsets. These conditions often develop after the traveler has returned home, because the short time required for air travel is within the incubation period of most infectious diseases, including malaria, kala-azar, pappataci (sandfly) fever, dengue, yellow fever, rickettsial infection, and bacillary and amebic dysentery. These returnees include soldiers, government employees, Point Four personnel, foreign visitors, missionaries, and tourists. Since World War II, over 2 million Americans have traveled outside the United States. Recently at the West Side Medical Center three Chicagoans were shown to have malaria after returning from visits to Mexico.

Political unrest and economic aid to underdeveloped countries require United States citizens to remain in endemic areas. Need of raw materials from countries where tropical diseases are prevalent demands that United States personnel be located in these countries. Men of the armed forces often are stationed in countries where these infections thrive. Each of these factors contributes to the redistribution of helminths.

Intestinal Parasites Now Common in North America

Formerly the most common pathogenic intestinal parasites found in persons in northern cities were Entamoeba histolytica, Giardia lamblia and Enterobius vermicularis. Now Ascaris lumbricoides, Ancylostoma duodenale, and Trichuris trichiura (whipworm) from the southern states are added. To a lesser extent, Schistosoma mansoni and Wuchereria bancrofti from endemic areas chiefly in the Western Hemisphere are added, as well as other parasites from Mexico, Japan, the Philippines, and countries all over the world.

Since about 1950 parasites have become more abundant and some hitherto unfamiliar parasites have appeared, for reasons enumerated above. A letter from Dr. Arthur E. Rikli of the regional office, Department of Health, Education and Welfare, states that 1,008 cases of schistosomiasis were recognized in members of the Army and 78 in the Navy between 1945 and 1954, chiefly in persons from Puerto Rico. In a survey of 16,000 Puerto Rican soldiers 14.6% showed S. mansoni infection. On the basis of autopsy findings, the incidence rose to 40%. Of 276 soldiers, 18.8% were passing eggs, while 43.5% showed positive skin tests.[10] It is generally assumed that the over-all population of Puerto Rico shows an infection rate of about 10%. Schistosomiasis is not reportable in Illinois, perhaps not in the United States, for it has never been endemic here, but it was placed on the exclusion list by the surgeon general of the U. S. Public Health Service in August, 1917. At the Research and Educational Hospitals in Chicago, the first cases of schistosomiasis was seen in 1950. In 1952, 'Vital Statistics of the United States,' volume 2,[11] showed three deaths due to schistosomiasis in white males.

In 1953 Shookhoff and others[12] said, "Among the parasitic diseases, bleeding from the rectum is most often due to schistosoma infections. S. mansoni is being seen with increasing frequency in the continental United States because of the presence of individuals from the endemic areas of the West Indies and South America." Meleny regards schistosomiasis as the most important disease of man, with the exception of malaria. Berry[13] states that schistosomiasis is the world's third most widespread disease, as it affects about 200 million people. At the Chicago Pathological Society on Feb. 13, 1956, Eisenstaedt, Bicknell, and Glasser[14] reported a case of schistosomiasis which was diagnosed post mortem. The patient entered the hospital in coma and died in a short time.

A comparison of the frequency with which the kinds of intestinal helminths were seen at Research and Educational Hospitals in Chicago during 1940 and 1942, as reported by the former parasitologist Dr. Marion Hood, and during 1950 and 1955 shows significant differences (see table). The results are based on stool examinations only.

The figures for the two periods are similar for the first five helminths listed, while Ancylostoma duodenale, Trichuris trichiura, and S. mansoni have been introduced into this region in increasing numbers. These three, plus Enterobius vermicularis, constitute the heaviest "worm burden" of the area. These parasites are undoubtedly present in much larger numbers than have been found.

Frequency with Which Intestinal Helminths Were Seen at Illinois Research and Educational Hospitals 1940 and 1942, 1950 and 1955

Type of Helminth	No. of Cases in	
	1940 and 1942	1950 and 1955
Taenia saginata	6	5
Hymenolepis nana	1	1
Strongyloides stercoralis	3	1
Enterobius vermicularis (pinworm)	40	39
Ascaris lumbricoides	4	0
Ancylostoma duodenale (hookworm)	1	23
Trichuris trichiura (whipworm)	1	43
Schistosoma mansoni	0	15

Survey of Incidence of Schistosomiasis.—In order to determine the number of cases of schistosomiasis which occurred in the Chicago area during 1955, a survey was made of 129 hospitals in Chicago and vicinity. Replies were received from 108 of these. Cook County Hospital reported 20 such cases. State institutions have diagnosed from 15 to 20 cases each year since 1950. Ten additional cases were diagnosed in other hospitals. Research and Educational Hospitals had 11 cases. This gives an estimated total of about 58 for the year. Several hospitals replied, "none that were recognized," and others replied, "none during 1955."

There are at least 22,000 persons in Chicago who have come from endemic areas of schistosomiasis. About 10% of these persons are thought to be infected. This means that about 2,200 persons in Chicago are harboring schistosomes. The calculated figure for New York City is approximately 70,000. Many of these persons have few or no symptoms, or they have had the symptoms so long that they consider themselves normal.

Only 17 of 89 consecutive patients from endemic areas of S. mansoni were found to have stools free of parasites. Twenty-one showed evidence of S. mansoni ova, 28 Ancylostoma duodenale, 54 Trichuris trichiura, 17 Giardia lamblia, 2 Strongyloides stercoralis, 1 Enterobius vermicularis, 3 Entamoeba histolytica, 3 Endolimax nana, 1 Dientamoeba fragilis, 1 Chilomastix mesnili, 5 Entamoeba coli, 1 Balantidium coli, and 1 Hymenolepis nana Of the 72 patients who showed evidence of parasites, 25 showed one type each, 31 showed two, 13 showed three, and 3 showed four

It must be remembered the 89 patients, among whom were several members of some families, presented gastrointestinal symptoms Also, only stools were examined If other methods of diagnosis, such as rectal biopsy and complement fixation, had been employed, the number of cases of schistosomiasis might have been higher Enterobius vermicularis is rarely diagnosed by stool examination The number of Entamoeba histolytica is less than expected This may be accounted for by the fact that most of the specimens were brought into the laboratory by clinic patients and were therefore too old for dependable protozal findings

A total of 13 different types of parasites were found in the 89 patients Two of these parasites, Endolimax nana and Chilomastix mesnili, are considered nonpathogenic The most common parasite, Trichuris trichiura, was found in 54 of the 89 patients Ancylosttoma duodenale was found in 28 patients and S mansoni in 21 Balantidium coli was found but once, at Research and Educational Hospitals, in May, 1956

Mode of Spread of Parasites

The mode of spread of parasites determines their effect upon the community The long-established intestinal protozoal parasites, Entamoeba histolytica and Giardia lamblia, multiply abundantly within the body and are easily passed to others through contaminated water and food, food handlers, and flies, and through personal contact

Enterobius vermicularis, the ubiquitous helminth, produces myriads of embryonated eggs The outstanding symptom is perianal pruritus, so there is anus to mouth infection, with abundant multiplication It spreads liberally by direct and indirect contact, especially in institutions for children This worm constitutes one of life's little irritations Most citizens live in comfort, while several million, chiefly children, carry on with indominable courage amid the misery of anal itching and intermittent diarrhea because they are harboring Enterobius vermicularis

Will the newly introduced parasites—Ancylostoma duodenale, Trichuris trichiura, and S mansoni—become endemic in the recently invaded areas? Most of the adult Ancylostoma will die within two years, but a few will survive for six years or even longer Because this parasite is not passed directly from person to person, but has a portion of its development outside the body, it is not likely to spread to contacts in areas where flush toilets are abundant It will flourish only where there is promiscuous defecation and people walk barefooted or there is other contact with skin, for the filariform larva gains entrance to the body through skin and mucous membranes If rules of sanitation and hygiene are followed, there should be little or no spread of Ancylostoma infestation

The life expectancy of the Trichuris is long, 20 to 30 years The worms often outlive the hosts Daily, large numbers of immature eggs, about 4,000 from each adult female, are discharged in the feces These ova mature and the larvae become infective in about 20 days The larvae enter the body by way of the mouth Light infections often are symptomless or produce vague abdominal pains, nausea, vomiting, and mild intermittent diarrhea In heavy infections the symptoms resemble those of Ancylostoma infestation Because these worms live for many years and the mode of entry is through the mouth, they are more apt to spread than Ancylostoma, especially among children in institutions Trichuris and their eggs will be present in newly invaded areas for years to come unless the patients are treated, and treatment is difficult and unsatisfactory T Pizzi[15] has shown that Trichuris trichiura is of historic importance He states that its eggs were found in abundance in the feces of the little Inca princess whose body was found well preserved by freezing, near Santiago, 17,658-ft elevation This find proves that Trichuris infestation was common in the Inca population before the Spanish conquest

Three important schistosomes infect man S mansoni, S japonicum, and S haematobium Morphologically these schistosomes look much alike and have similar life cycles The symptoms they produce vary somewhat, for they have different sites of predilection in the body Each of the schistosomes has characteristic ova The schistosomes are the most important trematodes that infest man In this group of flukes the individuals exist as males and females They are more worm-like and less leaf-like than the hermaphroditic flukes The size is variable, with lengths ranging from 6 to 25 mm The females are longer and slimmer than the males Schistosoma ova are not operculated "Schistosoma" means "slit body" and refers to the deep ventral groove forming the gynecophoral canal in the body of the male During copulation and oviposition the female lies within the gynecophoral fold of the male, and both worms reside within the blood vessels of man Both sexes are provided with oral suckers and acetabulums, but those of the males are larger and serve to anchor both worms during most of their lives

Schistosoma mansoni[16] has a complicated life cycle The adults live within the blood vessels When the female is ready to oviposit, the pair moves against the portal blood flow to the smaller vessels After an ovum is deposited, the female withdraws a little and discharges another, in bead-like formation When that vessel is filled with eggs, the worms back into another, and thus lay eggs in fan-like formation Many ova work their way through the capillary wall and ultimately reach the intestinal lumen and are discharged in the feces

To survive, the ova must reach fresh water The eggs are embryonated when passed, so they hatch soon The liberated miracidia swim about and penetrate snails of proper species Within the snail host they multiply through the larval stages In four to eight weeks forked-tail cercariae swarm from the snail during the sunlight hours The cercariae swim actively, tail first, until they reach the surface of the water Some adhere to the surface film, others drop to the bottom only to swim again to the top This vertical tour is repeated many times until they meet a host or perish Cercariae do not feed and can live only 12 to 16 hours in a free state

Cercarine have the power to penetrate human skin and mucous membranes Persons drinking, bathing, wading, or washing clothes in contaminated water are apt to be infected Barefoot farmers standing in irrigation ditches and cultivating rice fields are likely targets As the person emerges from the water, the water on the skin dries and the cercariae penetrate head first, leaving their tails outside Often there is some irritation of the skin caused by the entrance of cercariae Watercress grown in water containing infected snails is another source of infection

Within 24 hours after piercing the skin, some of the larvae have worked their way into the capillaries They are carried in the blood stream through the right side of the heart to the lung The disproportion existing between the diameter of the parasites and that of the lung capillaries may cause the parasite to remain in the lung for several days At times this causes symptoms similar to those of pneumonia Because the capillaries dilate and the worms elongate, they finally get through to the left side of the heart and into the systemic circulation It is believed most worms are destroyed Only the worms which reach the portal circulation survive Here, bathed in portal blood, they mature In about three to four weeks they leave the liver and go to mesentery of the large intestine En route the female is fertilized, so in another few weeks oviposition begins, thus completing the cycle

Schistosomiasis

Schistosomiasis caused by S mansoni, also called Bilharzia, is found in many parts of Africa, the West Indies, South America, and other scattered areas, chiefly in the tropics The symptoms depend upon the stage of the disease In the early stage there is leukocytosis with eosinophilia Later, leukopenia develops An increase in plasma globulin is characteristic At first the liver enlarges due to inflammation, for in the intrahepatic portal blood the adult worms produce metabolites which provoke an acute hepatitis and systemic intoxication Later there is extensive periportal fibrosis with compensatory congestive enlargement of the spleen and dilation of collateral veins Some ova are swept back into the liver Eggs in their course to the intestinal lumen cause traumatic damage and hemorrhage Later these areas may undergo malignant change Pseudo-tubercles form about trapped eggs Often ova are carried to the skin, where they ulcerate, and to the heart, where they cause myocarditis In fact, ova may be carried to any organ of the body, even to the central nervous system

A heavy infection of S mansoni produces fulminating bloody diarrhea followed later by cirrhosis of the liver, ascites, liver failure, and death A mild infection may produce few symptoms, but the paired worms go on continuously destroying blood vessels and laying eggs which are carried to liver, spleen, and elsewhere in the body As these worms live for 20 or 30 years, even a few of them may produce massive destruction

In the late stages of schistosomiasis, the abdomen is distended, while the arms and legs are emaciated Multiple fistulous tracts may develop about the anus, extending from the colon Diagnosis is confirmed by finding the characteristic ova in the stool Ova measure about 150 by 60 μ They are easy to identify because of the large, sharp lateral spine Other diagnostic procedures include rectal biopsy, complement fixation, precipitin test, and skin test Rarely, eggs or larvae may be found in the sputum (Infected persons should be treated not only for schistosomiasis but for all the parasites they harbor)

Complications include intestinal stenosis, hemorrhage, cor pulmonale, allergic manifestations, appendicitis, and malignant degeneration Death may be caused by overwhelming intoxication in the acute stage or cirrhosis of the liver, exhaustion, or intercurrent infection in the late stages

Possibilities of New Parasites Becoming Endemic

Whether schistosomiasis could become endemic in the United States is an important question This fluke has a complicated life cycle Feces containing viable eggs must reach fresh water The ova must hatch and the miracidia enter specific snails Development within the snail requires about one month Then the cercariae emerge in sunlight They must enter human skin within 16 hours to survive Studies by the National Institutes of Health made during World War II [17] indicate that there is a local species of snail capable of serving as intermediate host In order to establish an endemic focus, all of these conditions must prevail In spite of the presence of an appropriate snail, it seems unlikely that all of the factors necessary could conspire to establish a focus here

Of the three newly introduced parasitic worms—Ancylostoma duodenale, Trichuris trichiura, and S mansoni—the first and last are unlikely to become endemic because they have complicated life cycles and gain entrance to the body through the skin The cold of winter prohibits outdoor swimming and going barefooted, so any possible infection would be limited to the summer Both of these worms depend for their spread upon promiscuous defecation and unsanitary and unhygienic environment The other, Trichuris trichiura, because of its long life, simple life cycle, and mode of entrance through the mouth, has a possibility of spreading

At times, in spite of flush toilets and sanitation, there are small outbreaks of cases of infestation with unusual parasites, such as the one described by Dr L M Schuman of the Illinois Department of Public Health He made a preliminary report on a heavy infestation of Strongyloides stercoralis, primarily among inmates of a private mental institution in west central Illinois Toward the end of August a child developed a condition that was diagnosed as an upper respiratory infection of viral origin His condition failed to improve satisfactorily, and after several weeks the parents took him home There, the child was hospitalized, and, after the third week of hospital care, the larval form of Strongyloides stercoralis was observed in his stool An immediate survey of the three children's cottages with common playground facilities was made Among 82 child inmates, infestation with Strongyloides was noted in 38% on examination of initial stools It was stated that "this parasite apparently had never before been observed in the State of Illinois " Consequently, the roster of survey children was reviewed, and two children from New Mexico who had been admitted two months prior to this occurrence were found to be heavily infested with this parasite The investigation of this infestation was, at the time of this report, still in progress

Filariasis, Wuchereria bancrofti infestation, is not diagnosed by stool examination, so it is not within the scope of this paper However, it is found in many of the same areas as schistosomiasis The diagnosis is confirmed by finding the microfilaria in the peripheral blood at night It is transmitted from person to person by the common house mosquito, Culex fatigans As this variety is the usual pest mosquito, it would seem that filariasis would be more likely to spread here than schistosomiasis

The mixing of peoples and parasites is not a local problem Many Jamaicans are entering England, Indonesians are pouring into Holland, Algerians are flocking to France Perhaps it is another manifestation of 'one world

Comment

Worms do not have the universal appeal and journalistic value of great viral and bacterial epidemics Humans consider the subject unsympathetically and recoil at the thought of harboring worms But the helminths have resisted destruction and have persisted and multiplied since the beginning of time This is a tribute to their biological efficiency

Parasitism is allowed to persist because of lack of knowledge, lack of interest, poor diagnosis, and failure to realize the extent of misery caused by parasites The application of our present knowledge could eradicate most parasites from our country, just as malaria and yellow fever were eliminated, if interest were taken, known facts applied, treatment given, and preventive measures adopted

Summary and Conclusions

There has been an increased incidence of parasitic and tropical diseases in the United States A redistribution of helminths is partially responsible for the increase in parasitic diseases This redistribution is a result of several factors Masses of people migrating from the southern states to the northern states bring with them Ancylostoma duodenale (hookworm), Trichuris trichiura (whipworm), and Ascaris Thousands of people are arriving from the West Indies and other endemic areas, bringing with them Schistosoma mansoni, filaria, and other parasites Two million American tourists have visited foreign countries since World War II If they remain temporarily in endemic regions, they may bring the infections back with them Economic aid to underdeveloped countries requires that United States personnel travel to these countries Need of raw materials demands commercial representatives in endemic areas, and members of the armed forces often are stationed in such areas

Ameba, Enterobius vermicularis (pinworm), an Giardia have been present in northern cities for years Ancylostoma duodenale, Trichuris trichiura, and S mansoni began to appear about 1950 A survey o Chicago hospitals revealed 58 cases of schistosomiasi during 1955 The probable number of infected persons is 2,200, calculated on the percentage of thos harboring the parasite in the endemic areas fron which they came In New York City the calculate number of cases is 70,000 A study of the stools of 8 persons from endemic regions showed only 17 person without parasites, while 23% showed ova of S mansoni This group harbored 13 different types o parasites

The spread of parasites depends more on sanitatio and hygiene than on climate If the rules of sanitatio and hygiene are followed, these parasites are not likel to become endemic

DIAGNOSIS AND MANAGEMENT OF THYROIDITIS

James W. Hendrick, M.D., Tuscaloosa, Ala.

• *In 1,309 operations on the thyroid gland, various forms of thyroiditis were encountered in 117 patients, excluding 83 other patients in whom a focal thyroiditis was associated with diffuse toxic and adenomatous goiter and carcinoma. Among the 117 patients there were 28 with acute and 89 with chronic thyroiditis. The acute thyroiditis led to suppuration in 6 patients; they required surgical incision and drainage, and all recovered with the aid of antibiotics, chemotherapy, and supportive measures. There were 22 patients in whom the acute thyroiditis did not go on to suppuration; antibiotic and x-ray therapy sufficed in 8 of these, but surgery was necessary in 14. The 89 patients with chronic thyroiditis were classified, upon examination of tissues removed at operation, as having Hashimoto's disease in 67, giant cell thyroiditis (granulomatous thyroiditis) in 16, and Riedel's struma in 6 cases. Surgical treatment of these forms of chronic thyroiditis is necessary in order to restore a normal appearance to the neck, to relieve pressure especially on the trachea, and to obtain adequate tissue specimens for diagnosis. Aspiration biopsies have not always yielded adequate specimens, and radiation therapy given in quantities sufficient to reduce the size of the thyroid also reduces its function. In this series of cases there were neither operative deaths nor serious postoperative complications.*

Recognition of the various forms of thyroiditis is essential to the clinician, surgeon, and pathologist in the management of diseases of the thyroid gland. The original reports of Riedel, a German surgeon,[1] Hashimoto, a Japanese surgeon,[2] and DeQuervain, a Swiss surgeon, and Giordanengo[3] have contributed greatly to our knowledge of thyroiditis.

The purpose of this report is to evaluate the histories, clinical and operative findings, pathological patterns, follow-up reports of, and therapy administered to a group of patients with thyroiditis in order to develop conclusions and correlate clinical findings that will be of value in the management of patients with this disease.

In 1,309 consecutive operations on the thyroid gland performed by me between the years 1933 and 1955, acute, subacute, and chronic thyroiditis were encountered in 117 patients. Eighty-three other patients were found to have focal lymphoid thyroiditis associated with diffuse toxic and adenomatous goiter and carcinoma of the thyroid gland. This latter group of patients, along with six others who had been treated elsewhere with radioactive iodine (I^{131}) for diffuse toxic goiter and who developed, after a period of from three to six years, large, firm goiters requiring bilateral subtotal thyroidectomy for relief of symptoms, are not included in this report.

The clinical and pathological classification of thyroiditis that I have utilized and found to be comprehensive consists of two large divisions. The first type is acute thyroiditis, consisting of acute suppurative thyroiditis and acute nonsuppurative thyroiditis. In this series there were 6 cases of the former and 22 of the latter. *The second type is chronic thyroiditis.* Under this classification there were in this series 16 cases of granulomatous or giant cell thyroiditis, 67 cases of Hashimoto's disease or struma lymphomatosa, and 6 cases of Riedel's struma.

Acute Thyroiditis

Acute suppurative or nonsuppurative thyroiditis, which follows an upper respiratory infection, is probably embolic in origin.[4] This form of thyroiditis is manifested by tenderness and pain in one or both lobes of the thyroid gland, hoarseness, local evidence of inflammation, painful swallowing, elevation of temperature, increased pulse and sedimentation rates, and spasm of the prethyroid and sternomastoid muscles. As the disease progresses the outline of the gland is masked by edema, which prohibits accurate delineation of the extent of the disease.

Acute Suppurative Thyroiditis.—The six patients, four males and two females, with acute suppurative thyroiditis developed an abscess, which required drainage. When first observed, they were all very ill, with severe pain, hoarseness, dysphagia, elevated temperature and pulse rate, and chills; the head was flexed toward the involved side, and in each instance the thyroiditis was a sequela of an upper respiratory infection. The disease remained localized to one side in all six patients, none of whom required thyroidectomy. Each made an uneventful recovery from the operative procedure necessary for drainage and was dismissed from the hospital within a period of six to seven days. None of these patients had any further difficulty relative to the thyroiditis. This form of the disease may be observed in any age group, the average age at operation of the patients in this series being 44 years.

Acute Nonsuppurative Thyroiditis.—Of the 22 patients, 8 males and 14 females, with acute nonsuppurative thyroiditis (fig. 1), 17 had unilateral involvement of the thyroid gland and 5 had bilateral involvement. Upper respiratory infection preceded the disease in all 17 cases. The patients in this group were not so ill as the six patients described previously who developed suppuration and required surgical incision and drainage. The thyroid gland of these patients was enlarged, tender, and painful, resulting in dysphagia in 21 patients and hoarseness in 17, while in 6 patients it was difficult to differentiate between thyroiditis and anaplastic carcinoma.[5] Sixteen patients had an elevated

Read before the Section on Surgery, General and Abdominal, at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956.

temperature and pulse rate, and six had chills Twelve of the patients underwent hemithyroidectomy and two bilateral subtotal thyroidectomy The ages of patients with this form of thyroiditis varied from 16 to 68 years, the average age at operation in this series being 40 years

Chronic Thyroiditis

The incidence of the three forms of chronic thyroiditis, that is, granulomatous or giant cell, Hashimoto s disease or struma lymphomatosa, and Riedel's struma, apparently is on the increase Chesky and co-workers[6a] reported on 169 cases encountered in 2,031 patients requiring thyroidectomy in a 10-year period, or an incidence of 8 3% I encountered the various forms of chronic thyroiditis in 89 patients in a total of 1,309 thyroidectomies, or 6 8% The disease is more frequently encountered along the Gulf Coast than in other sections of the United States

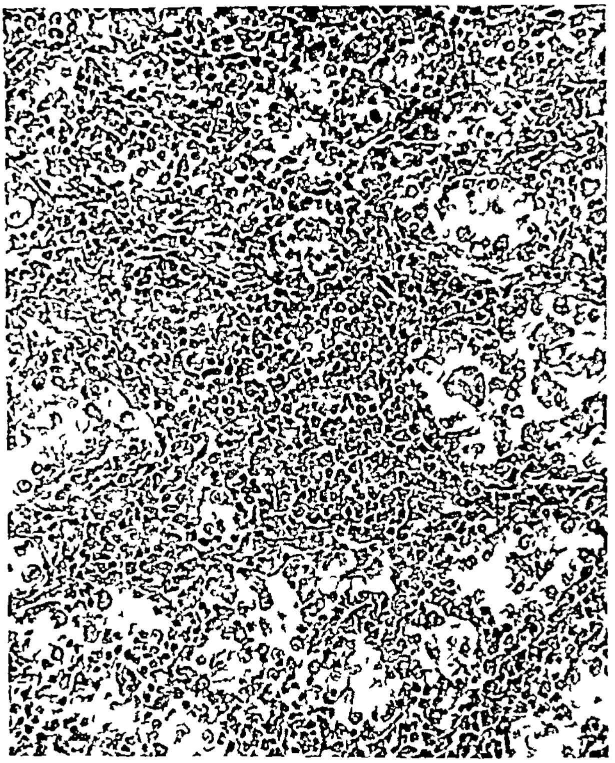

Fig 1 —Photomicrograph in acute nonsuppurative thyroiditis, demonstrating extensive degeneration of thyroid follicles with invasion of stroma with inflammatory cells This type of severe infection permanently destroys involved area of thyroid

There have been numerous controversial reports on these three forms of thyroiditis relative to etiology, classification, pathogenesis, and therapy[6] In the past few years, thyroidologists have made a continuous study of this form of thyroid pathology and constructive work has been accomplished[7] Chronic thyroiditis is manifested by the presence of lymphoid infiltration, epithelial alterations, and various degrees of fibrosis[8]

Granulomatous or Giant Cell Thyroiditis—There were 16 patients with granulomatous thyroiditis in this group Females were more frequently affected than males, the former numbering 10 and the latter 6 The youngest patient was 28 years of age and the oldest 62 (table 1) This disease is a distinct clinical entit of unknown etiology It has been suggested by som that it is produced by a viral, chemical, or bacteria agent, however, none has been recovered from resected specimens[9]

The clinical course of granulomatous thyroiditis which frequently follows an upper respiratory infection, is sudden onset with rather marked systemic reaction The patient feels nervous, weak, and tired, an the pulse rate may be elevated out of proportion t the temperature[10] The disease begins in one lobe an may gradually extend to involve the entire gland, does not originate in a gland that has been previousl involved by a goiter

Table 1 —*Various Time Elements in Regard to Patients wit Different Forms of Chronic Thyroiditis*

	Granulomatous or Giant Cell Thyroiditis	Hashimoto s Disease or Struma Lymphomatosa	Riedel Struma
Av duration of goiter yr	2	3 6	2
Av duration of symptoms yr	8 mo	3	2
Av age at operation yr	42	51	48
Age of youngest patient yr	28	20	40
Age of oldest patient yr	62	69	65

Tenderness and pain were present in one or bot lobes of the thyroid gland in all 16 patients, 9 complained of voice changes or hoarseness (table 2 In one patient, in whom the disease was unilatera there was paralysis of the vocal cord on the affecte side Twelve patients complained of painful swallowing, which resulted in weight loss, and 14 had pressu symptoms or were nervous The sedimentation ra was increased in 12 patients, the basal metabolic ra was below -10% in 12 patients, and the protei bound iodine determination was normal in the 1 patients on whom the test was performed (table 3

The thyroid gland was definitely enlarged in all patients, in nine the disease was unilateral and in seve it was bilateral The enlargement was not pronounce

Table 2 —*Symptoms in Patients with Different Forms of Chronic Thyroiditis*

	No of Patient with		
	Granulomatous or Giant Cell Thyroiditi	Hashimoto s Disease or Struma Lymphomatosa	Riedel Strum
Pain or tenderness in thyroid gland	16	56	6
Referred	16	22	6
Hoarseness or voice changes	9	8	5
Vocal cord pathology (unilateral)	1	3	2
Pressure symptoms	14	28	6
Difficulty in swallowing	12	10	6
Anxiety state with nervousness	12	44	2

the average resected lobe weighed only 25 to 30 Gr The gland was fixed, tender, and not infrequently difficult to differentiate from carcinoma when there wa unilateral involvement A correct preoperative diagnosis was made in eight cases At operation there we adhesions involving adjacent structures, i e, pr thyroid muscles, cervical fascia, and carotid sheat

Pathological examination revealed the glands to b smooth and firm to hard but not of the consistenc observed in Riedels struma There were no nodule and the color of the specimens varied from white t yellow to pink Microscopic examination revealed degeneration of the follicular epithelium with desquamation of the epithelial cells accompanied by a neutrophilic and eosinophilic infiltration (fig 2) Large peculiar multinucleated syncytial giant cells, which appeared to be foreign body giant cells, were also present, these, in all probability, are produced by macrophages phagocytizing colloid in the degenerated follicles The presence of these foreign body giant cells has given rise to the names pseudotuberculous, granulomatous, or giant cell thyroiditis In glands in which the disease had been present for long periods of time there was marked fibrous replacement of epithelial tissue

Hashimoto's Disease or Struma Lymphomatosa—After the description in 1912 of Hashimoto's disease,[7] very little attention was directed to it as a pathological entity until Graham[11] demonstrated in 1931 that Riedel's struma and struma lymphomatosa were distinct and distinguishable diseases He reported 24 cases of struma lymphomatosa encountered in 114 cases of chronic thyroiditis at the Cleveland Clinic Joll,[6d] in 1939, made an extensive study of the pathological and clinical manifestations of this disease and stated that in all probability Hashimoto had only described the earlier phase of this form of thyroiditis, he reported 81 cases

Hashimoto's disease, or struma lymphomatosa, is the most frequent form of chronic thyroiditis Davison and Letton,[12] as well as other observers,[13] have shown that the disease is definitely on the increase, they found that the incidence in their practice increased remarkably after the beginning of World War II It is thought that in all probability the vicissitudes and stress and strain of the war acted as precipitating factors in the production of the disease

In my series there were 67 patients, 4 males and 63 females, with Hashimoto's disease, the average age for the entire group was 51 years (table 1) The youngest patient observed by me was an 8-year-old female who had the right lobe of the thyroid gland removed for a discrete adenoma by Dr James Pridgen Jr at the Baptist Memorial Hospital in San Antonio, Texas Histological examination of tissue revealed early Hashimoto's disease The left lobe was not enlarged nor removed, however, two years later it became enlarged and firm, at which time it was removed Histological examination revealed typical early Hashimoto's disease, and an area of tissue approximately 3 mm in diameter showed papillary adenocarcinoma

TABLE 3—*Laboratory Studies on Patients with Different Forms of Chronic Thyroiditis*

	No of Patients with		
	Granulomatous or Giant Cell Thyroiditis	Hashimoto's Disease or Struma Lymphomatosa	Riedel's Struma
Elevated sedimentation rate	12	8	4
Preoperative B M R			
Above +10%	2	8	1
Below —10%	12	51	5
Preoperative serum cholesterol level			
Above 200 mg per 100 cc	12	56	5
Below 200 mg per 100 cc	2	4	1
Preoperative protein bound iodine level			
Above 6 µg per 100 cc	0	2	0
Below 6 µg per 100 cc	8	28	0
Postoperative B M R			
Above +10%	1	6	0
Below —10%	12	52	5

The average duration of the goiter in this series was 3½ years, the duration of symptoms was from 2 months to 20 years (table 1) Twenty-one patients had unilateral involvement and 46 bilateral involvement Ten patients had difficulty in swallowing, and 28 had pressure symptoms Forty-four complained of nervousness and an anxiety state In eight patients there were voice changes and hoarseness, three of these had unilateral vocal cord pathology (table 2) A correct preoperative diagnosis was made in 24 of the 67 cases At operation, there was involvement of adjacent structures in 16 patients

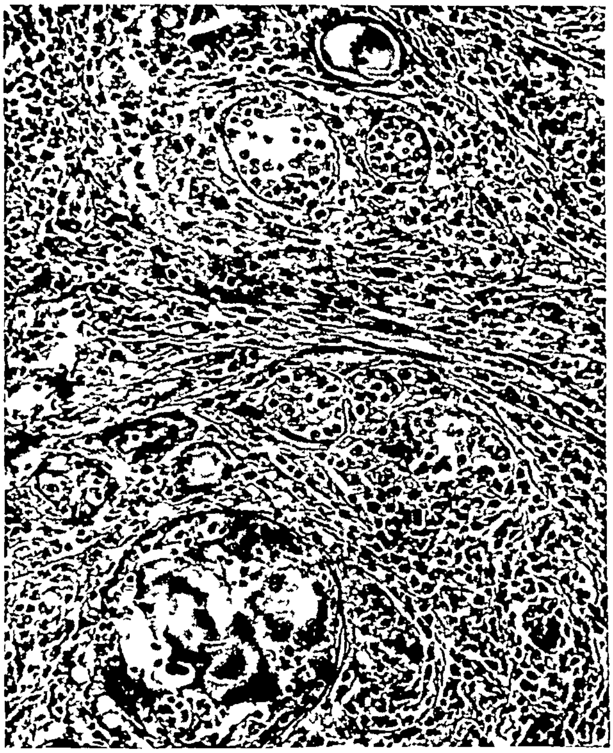

Fig 2—Photomicrograph in granulomatous or giant cell thyroiditis demonstrating invasion of stroma with neutrophilic and eosinophilic leukocytes and fibroblasts Most of the thyroid follicles have been disrupted Macrophages are seen engulfing colloid

Hashimoto's disease is definitely a degenerative type of chronic thyroiditis The patients who were observed in the early stage of the disease had a peculiar type of hypometabolism that did not respond well to thyroid medication In 51 patients the preoperative basal metabolic rate was below −10%, in 56 patients the serum cholesterol level was above 200 mg per 100 cc, and in 30 patients on whom the examination was performed the protein-bound iodine level was within normal limits (table 3)

None of the patients gave a history of infection preceding enlargement of the thyroid gland, this is in contrast to patients with granulomatous thyroiditis There was no clinical evidence to suggest that Hashimoto's disease resulted from thyrotoxicosis, either of the diffuse or adenomatous type The most frequent complaints were development of a goiter, choking or pressure sensation, nervousness, fatigue, and gain of weight associated with the hypothyroidism present in most cases, some few patients had difficulty in swallowing and others complained of tenderness of the thyroid gland (table 2) There was enlargement of the gland in every case, and in some it was quite pronounced When only one lobe of the gland was involved, a unilateral adenoma was thought to be present

Diagnosis of Hashimoto's disease should not be difficult if considered by the examiner, it more frequently occurs in women past 40 years of age who develop a painless enlargement of one or both lobes of the thyroid gland not associated with thyrotoxicosis and without evidence of inflammation The gland is of normal contour there may be marked enlargement of one lobe, which may occasionally cause this disease to be confused with carcinoma The sedimentation rate in this group of patients was normal in all but eight, in whom it was elevated (table 3)

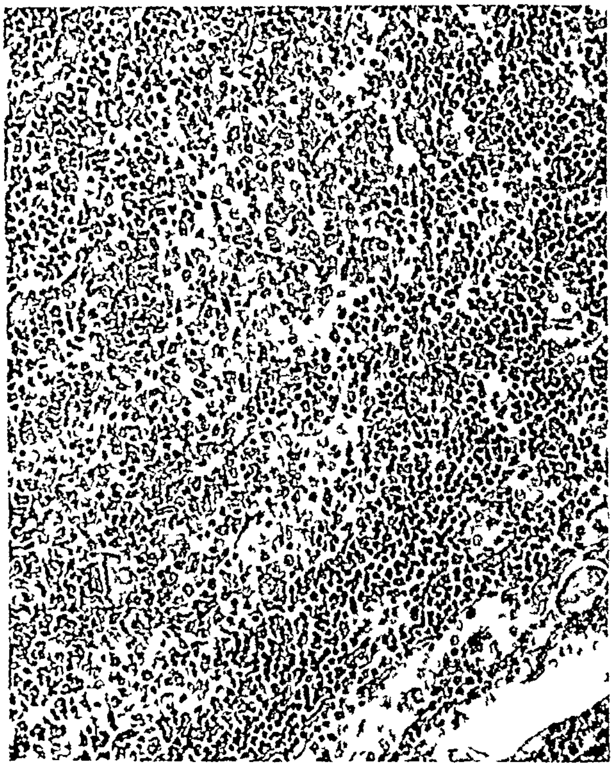

Fig 3 —Photomicrograph in early Hashimoto's disease or struma lymphomatosa demonstrating diffuse invasion with lymphocytes and plasma cells Only a few small thyroid follicles remain

Grossly, the gland is enlarged, all parts of one or both lobes are affected The resected glands varied from 25 to 190 Gm in weight, the surface was smooth and slightly lobulated The superficial veins were not enlarged as they are in toxic goiters The gland was more firmly attached to the trachea than normally and adhered to adjacent structures in 26 patients The clinical history of these 26 patients showed that they had had the disease for a longer period of time, and there was more fibrosis present than in patients whose disease was of short duration In the earlier stage of the disease the gland was friable, the capsule was thin, and the severed surface was lobular with a yellowish or brownish appearance The older glands were tougher and more resilient, but they did not have the hardness encountered in Riedel's struma

Microscopically, early Hashimoto's disease, which is of a degenerative nature, demonstrates a diffuse lymphocytic infiltration that involves all of each lobe with lymph follicles varying in size and number There are a few normal-appearing small epithelial follicles containing a scant amount of colloid Other epithelial follicles are disrupted, the epithelial cells lie in small irregular groups The supporting stroma is infiltrated with plasma cells and lymphocytes (fig 3) In some glands there are areas in which there appears to be regeneration, the thyroid follicles, although small, have regained a normal appearance[14] In older glands the lymphoid components are definitely decreased There are fewer thyroid follicles with more fibrosis Apparently, in cases of long standing, the disease has extended through cycles of exhaustion, repair with some return of function, but later regression and more fibrosis[6e]

Riedel's Struma—Riedel's struma is an invasive fibrous type of thyroiditis of unknown etiology that may involve one or both lobes of the thyroid gland The disease manifests itself by a sclerosing process, which eventually strangulates and destroys the thyroid parenchyma, thereby resulting in a mass of dense fibrous tissue resembling soft wood (woody thyroiditis) It may begin in the interior of the gland, frequently around a small degenerating adenoma, with outward spread, or else it may begin superficially and extend inward to involve the entire lobe or gland, it may simulate a slowly developing carcinoma

The involved lobe or lobes are not appreciably enlarged Adjacent tissues are invaded early by fibroblasts causing symptoms of tracheal obstruction, pressure on the esophagus producing dysphagia, and not infrequently compression of the internal jugular veins In my series, there were six patients, three males and three females, with invasive fibrous thyroiditis, three had unilateral involvement and three bilateral Two had unilateral involvement of the recurrent laryngeal nerve with vocal cord pathology (table 2) Five of the six patients had hoarseness, and all complained of severe pressure (table 2) When the lesion is limited to one lobe there may be tracheal displacement Pain is a common symptom and is referred to the back of the neck, shoulder, or angle of the jaw Dyspnea is a striking feature when there is bilateral involvement with anterior-posterior or bilateral compression of the trachea

There was evidence of hypothyroidism in five of the six patients, they had a basal metabolic rate below −10% with elevation of the serum cholesterol level above 200 mg per 100 cc (table 3) In two patients the disease developed in a goitrous gland A correct preoperative diagnosis was made in four patients, the other two were thought to have carcinoma The average age was 48 years (table 1) The disease had been present for an average of two years at the time I first saw the patients

At operation all patients had invasion and infiltration of the strap muscles, midcervical fascia, and carotid sheath resulting in an indefinite line of cleavage Frequently it was almost impossible to find a natural line of cleavage between the tissues, especially in patients in whom the disease had been present for some period of time The gland was white in color, hard, and avascular, in two patients there was an adenoma that had undergone degeneration in the center of the lobe Histological examination revealed destruction of the thyroid epithelium, with invasion by fibroblasts, inflammatory cells, monocytes, large lymphocytes, and some plasma cells (fig 4) Few capillary blood vessels remained

Lahey[15] described well the etiology of the pressure symptoms in invasive fibrous thyroiditis or other forms of thyroiditis when the gland is replaced by fibrous tissue In view of the fact that the thyroid gland surrounds at least two-thirds of the trachea, when an inflammatory process develops in both lobes and the isthmus of the gland, its normal attachments to the trachea become more firm, thereby resulting in pressure and constriction

Treatment of Acute Thyroiditis

Acute Suppurative Thyroiditis—The treatment of acute suppurative thyroiditis consists of adequate administration of antibiotics, chemotherapy, and supportive measures When there is definite abscess formation, incision and drainage of the abscess is imperative The abscess is drained through a collar incision, the skin flaps are dissected up and downward In each case, the midcervical fascia and prethyroid and sternomastoid muscles were adhered to the involved lobe of the thyroid gland A longitudinal incision is made through the prethyroid muscles to the abscess cavity Care is exercised not to break down the walls of the cavity, that would result in a mediastinitis, which could be fatal This method of treatment was utilized in the six patients with suppurative thyroiditis They made an uneventful recovery, four required desiccated thyroid extract for the control of hypothyroidism

Acute Nonsuppurative Thyroiditis—The treatment of acute nonsuppurative thyroiditis consists of adequate antibiotic therapy and x-ray therapy, with 150 r given three times weekly for a total of approximately 1,200 r over the involved lobe or lobes of the thyroid gland Corticotropin (ACTH) and cortisone were given a generous trial but proved to be of no value If the symptoms persist after a period of six to eight weeks, more definitive therapy is essential Eight patients in this series responded to the above-mentioned medical measures, 12 patients required hemithyroidectomy and 2 bilateral subtotal thyroidectomy These patients had a normal convalescence The clinical diagnosis was confirmed by aspiration biopsy in the eight patients who responded to medical measures The patients who demonstrated hypothyroidism after recovery from the disease were placed on therapy with desiccated thyroid extract, 1-3 grains (60 mg -200 mg) daily depending on the individual requirement

Treatment of Chronic Thyroiditis

Every thyroidologist has observed in his practice a considerable number of patients who have been given a clinical diagnosis of mild chronic thyroiditis These patients have few symptoms Their goiters are small, pressure symptoms are minimal, and there is no evidence of malignancy When the clinical diagnosis is established and the goiter is small and not unsightly and gives no pressure symptoms, surgical measures are postponed, these patients, most of whom have a thyroid deficiency, are given desiccated thyroid extract when there is proof of a thyroid deficiency

For some period of time aspiration biopsy was utilized to establish a diagnosis in the various forms of thyroiditis In five patients aspiration biopsy demonstrated either granulomatous thyroiditis or Hashimoto s disease, but later carcinoma was found to be present consequently, I no longer recommend this method of obtaining biopsy material In several instances it was difficult, histologically, even after thyroidectomy, to differentiate between certain cases of chronic thyroiditis and anaplastic carcinoma Bellegie and co-workers,[16] at the Mayo Clinic, have encountered the same difficulty in differentiating between these two diseases

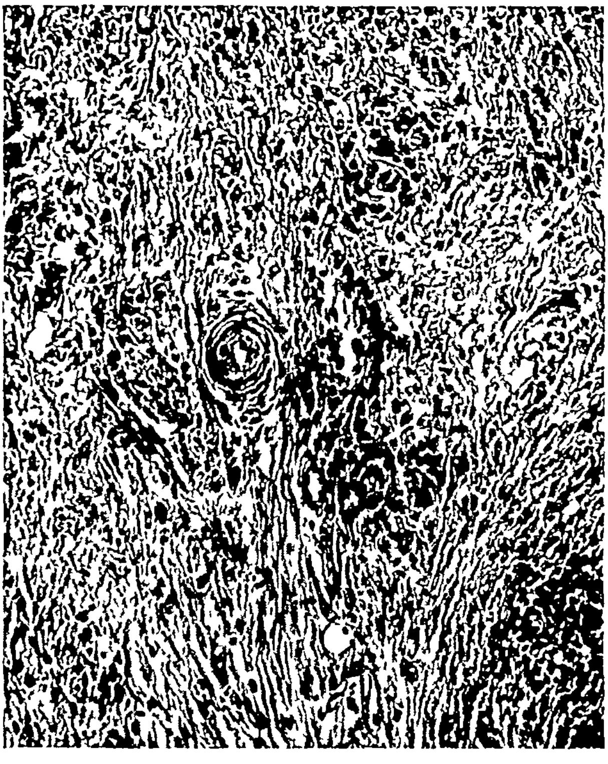

Fig 4—Photomicrograph in Riedel s struma, demonstrating diffuse invasion of thyroid tissue by fibroblasts, leukocytes, and lymphocytes with no functioning thyroid parenchyma remaining

Surgical treatment of chronic thyroiditis should be undertaken for the following reasons (1) for cosmetic purposes when the goiter is large, (2) to relieve pressure symptoms and decompress the trachea, and (3) to determine by histological examination of tissue that the enlargement is not produced by carcinoma[17]

Granulomatous or Giant Cell Thyroiditis—The 16 patients with granulomatous thyroiditis had sufficient symptoms to require surgical treatment In nine patients there was unilateral involvement, consequently, only a hemithyroidectomy was necessary In the remaining seven patients there was bilateral involvement, and a subtotal thyroidectomy was performed

Hashimoto's Disease or Struma Lymphomatosa.—Thyroidectomy was performed on all 67 patients with Hashimoto's disease. Twenty-one appeared to have only unilateral involvement, and hemithyroidectomy was performed; 46 had bilateral involvement, and subtotal thyroidectomy was performed. Six patients, whose disease apparently was unilateral and who had hemithyroidectomy, later developed the disease on the opposite side, thus requiring hemithyroidectomy on the remaining lobe. In two of these patients the intervals between the first and second operations were 14 and 18 years respectively. At the time the initial surgery had been performed, histological findings in these two cases had demonstrated marked lymphocytic infiltration with germinal centers present, thus denoting the earlier form of the disease. Histological examination of the opposite lobes, removed 14 and 18 years later, demonstrated that the gland in each case had been practically replaced with fibrous tissue, thus denoting the advanced stage of the disease.[7b] If surgical treatment is required, it is my practice at the present time to perform a subtotal thyroidectomy and not a hemithyroidectomy because of the great likelihood of future involvement of the opposite lobe, which would require a second operative procedure at a later date.

Riedel's Struma.—Hemithyroidectomy is recommended for patients with Riedel's struma who have unilateral involvement; if there is bilateral involvement the technique recommended is the one advocated by Lahey[15] in which the entire thyroid isthmus and as much as possible of each lobe is resected. Care must be exercised to avoid leaving any of the isthmus adhering to the trachea, so that the trachea is left entirely free from any adherent thyroid tissue. The edges of the severed lobes are then sutured with fine absorbable surgical sutures to prevent hemorrhage; the medial edges of the sternohyoid muscles are sutured to the trachea to cover the severed ends of each thyroid lobe. This prevents thyroid tissue from reuniting across the anterior surface of the trachea. The bellies of the prethyroid muscles and the medial portion of the sternomastoid muscles are pulled together and sutured to prevent the upper skin flap from becoming adhered to the trachea and bobbing up and down when the patient swallows. This technique gave satisfactory results in the three cases of bilateral Riedel's struma.

During the period of time that I used aspiration biopsy for diagnosis of chronic thyroiditis, radiation therapy was administered over a period of three to four weeks, with an average dose of from 1,500 to 2,000 r. It was observed that roentgen therapy produced a decrease in the size of the thyroid gland in some patients but that later thyroidectomy was necessary to relieve the pressure symptoms that were present. Histological examination of tissue demonstrated less functioning thyroid epithelium and more fibrosis than was present in the original material from aspiration biopsy. It is my contention at the present time that irradiation therapy in quantities sufficient to produce shrinkage of the thyroid gland further destroys the already embarrassed thyroid epithelium, and I no longer use this form of therapy. Desiccated thyroid extract was administered when indicated. Corticotropin and cortisone were utilize in a small group of patients with Hashimoto's diseas and granulomatous thyroiditis, with no relief of symptoms or change in consistency of the gland.

Postoperative Complications

There was no operative mortality in the group o patients who underwent thyroidectomy. Six patient had unilateral vocal cord paralysis before operation—one with granulomatous thyroiditis, three wit Hashimoto's disease, and two with Riedel's strum (table 2). This complication remained after thyroidectomy; there were no operative injuries of th recurrent laryngeal nerves. Laryngeal edema developed after operation in six patients, in two after drainage of abscess for acute suppurative thyroiditis, in tw with granulomatous thyroiditis, and in two wit Hashimoto's disease. Tracheostomy was not necessar in any of these. After operation, three patients developed transient tetany, one with Hashimoto's diseas and two with extensive bilateral Riedel's struma. Thi complication responded to medical measures within a period of eight weeks after operation.

Hypothyroidism was frequently encountered in al three types of chronic thyroiditis before and afte surgical treatment, as demonstrated by clinical examination and laboratory procedures consisting of determinations of basal metabolic rate, serum cholestero level, and, in some cases, protein-bound iodine. When a patient had clinical evidence of marked hypothyroidism or myxedema, characterized by intolerance to cold, fatigue, alopecia, marked dryness and roughness of the skin, a significant gain in weight, and, in some cases, swelling of the tongue causing slow slurred speech, he was placed on therapy with desiccated thyroid extract with commendable results.

Comment

In 1,309 consecutive operations on the thyroid gland performed between 1933 and 1955, various forms o thyroiditis were encountered in 117 patients. Acute suppurative and nonsuppurative thyroiditis most frequently follow an upper respiratory infection and are manifested clinically by tenderness and pain in one o both lobes of the thyroid gland. Local evidence o inflammation is present, dysphagia and, not infrequently, elevation of temperature and pulse rate occur. Six patients with acute thyroiditis developed suppuration with abscess formation. After sufficient response to medical measures, i.e., administration of antibiotics, chemotherapy, and supportive measures drainage of the abscess was necessary.

Twenty-two patients with acute nonsuppurative thyroiditis were treated with antibiotic therapy, cortisone, corticotropin (ACTH), and antithyroid drug were administered without results. Fourteen patient did not respond to medical therapy, and the disease persisted. Twelve required hemithyroidectomy and two bilateral thyroidectomy.

Chronic thyroiditis is divided into three groups granulomatous or giant cell, Hashimoto's disease o struma lymphomatosa, and Riedel's struma. Granulom atous thyroiditis has been designated as pseudotuberculous or giant cell thyroiditis because of the presence of large multinucleated giant cells This disease frequently follows an upper respiratory infection, its etiology is unknown The treatment is hemithyroidectomy when the disease is limited to one lobe or bilateral subtotal thyroidectomy when both lobes are involved

Hashimoto's disease or struma lymphomatosa was the most frequent form of thyroiditis encountered It is definitely a degenerative disease, one or both lobes of the gland gradually enlarge and are smooth and nontender, after a period of time, pressure symptoms develop Not infrequently the gland reaches a very large size The majority of the 67 patients with Hashimoto's disease were women past the childbearing age These patients have a peculiar type of hypometabolism, in some progressing into myxedema Microscopically the early phase of the disease is *manifested by a diffuse lymphocytic infiltration of the* gland, with varying numbers of germinal centers and with few remaining epithelial follicles In the later phase, the lymphoid components are replaced by fibrosis with few functional thyroid follicles remaining Patients with small, smooth glands and without symptoms of pressure or without evidence of carcinoma are treated medically and observed at intervals If the gland is large and unsightly and gives pressure symptoms or if doubt exists whether carcinoma is present, operation is advised, a subtotal thyroidectomy gives the best results

Riedel's struma or fibrous invasion thyroiditis was encountered in six patients The disease was unilateral in three and bilateral in three At operation there was invasion and infiltration of the cervical fascia, strap muscles, trachea, and carotid sheath, with an indistinct line of cleavage If the disease is unilateral, an attempt is made to do a hemithyroidectomy, when the disease is bilateral, the operative procedure developed by Lahey[15] gives the best results In this procedure the isthmus and as much of each lateral lobe of the thyroid as possible are resected The prethyroid muscles are sutured to the tracheal fascia and to the edges of the severed lobes in order to prevent the thyroid tissue from reuniting across the anterior surface of the trachea and to eliminate pressure symptoms

For a period of time, I used aspiration biopsy to establish a diagnosis in chronic thyroiditis Five patients whose initial diagnosis, established by aspiration biopsy, was made by me and three others referred to me after diagnosis was established by this method were judged to have either granulomatous thyroiditis or Hashimoto's disease Later these patients were found to have carcinoma, consequently, I no longer advocate this method of obtaining material for histological study

Radiation therapy was formerly utilized in the treatment of granulomatous or Hashimoto's thyroiditis after diagnosis was established by aspiration biopsy In both of these forms of thyroiditis the thyroid gland is already embarrassed and in a state of hypofunction Irradiation therapy given in quantities sufficient to produce any reduction in size of the gland only further serves to destroy the remaining thyroid epithelium and reduce thyroid function Consequently, I do not use irradiation or radioactive iodine (I^{131}) in the treatment of granulomatous or Hashimoto s thyroiditis The antithyroid drugs, corticotropin (ACTH), and cortisone have been used, but without benefit, to relieve symptoms or to reduce the size or consistency of the gland There were no operative deaths in this series of patients with thyroiditis who were treated, and no serious complications resulted from the operative procedures

CLINICAL EVALUATION OF SCOLIOSIS

Joseph C Risser, M D, Pasadena, Calif

• Early recognition of scoliosis is possible if the back is examined with the patient bending forward This should be part of every physical examination in children Deformity increases most during the period of rapid vertebral growth from 11 to 15 years of age unless it is corrected The severity of scoliosis is expressed in degrees of angular measure as determined on the roentgenogram If it exceeds 30 degrees, complete restoration is no longer likely to be achieved because the average amount of correction obtained by traction, body casts, and surgical fusion of the affected vertebrae is about 25 degrees The use of a localizer cast makes it possible to keep the patient ambulatory all the time, except for the 7 to 10 days after surgery The total period of immobilization of the patient's back after operation is 8 to 10 months

The clinical evaluation of scoliosis is dependent upon the information about the condition in general and of the patient in particular Our first duty to the scoliotic patient is the recognition of the deformity and the determination of whether the deformity is postural or structural By having the patient bend forward one can recognize easily the presence of an asymmetry of the two sides of the back (fig 1) This bending should be done in every examination of a child If the deformity of the spine disappears and if there is no unilateral deformity in this forward-bend position, it is postural If the asymmetry is very slight and the curvature is 10 degrees or less, much can be accomplished with stretching and postural recumbent and hyperextension exercises in these early cases where structural deformity is minimal or has not occurred (fig 2)

Scoliosis is commonly detected when the deformity becomes noticeable, at about 25 or 30 degrees At this time structural wedging has already occurred, with apical vertebral rotation (fig 3) With this severity correction is only possible with traction and lateral bend, as in the turnbuckle cast or the localizer cast

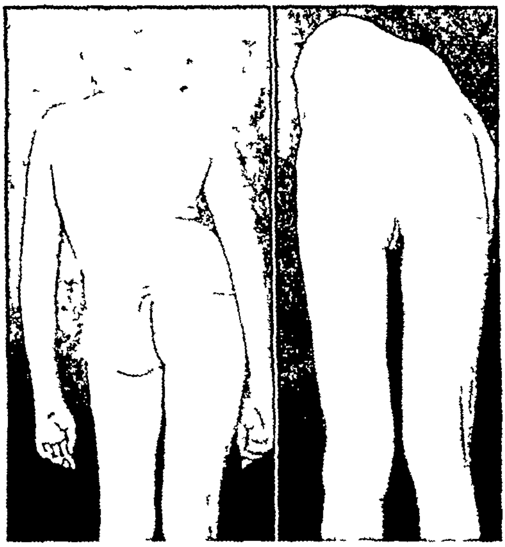

Fig 1 —Recognition of scoliosis by having patient bend forward Note unevenness of right and left sides of back

Without treatment increasing deformity will occur with vertebral growth Since growth is segmental, there is usually a slow growing period from the age of 6 to 10 years, with little increase in the curvature However, with rapid vertebral growth, during the period from 11 to 15 years (fig 3), there may be and commonly is a rapidly increasing deformity The deformity may be made much worse, even in slow growing periods, by the poor integrity or structure of bone due to deficiency disease (fig 4)

Comparative vertical height measurements, standing, sitting, and kneeling, are helpful in getting information about growth of the patient The initial examination of a patient should also include a standing anteroposterior roentgenogram to show the condition's true severity and a lying anteroposterior view to show how much natural relaxation or correction occurs A lateral view of the spine gives information about the presence of anteroposterior curves and also about the type of bone present Bone showing epiphysial fragmentation and delay in development, as well as osteoporosis, will allow a more rapid increase with vertebral growth Cessation of vertebral growth is determined by comparative height measurements Roentgenographic evidence of presence of the iliac apophysis gives advance notice to the completion of vertebral growth Since a scoliotic deformity is static with growth completion, treatment is not necessary in these cases, except to gain and maintain correction or to relieve pain that might be present in the adult patients

The decision to correct the deformity must be left to the patient, after he has received sufficient information on the amount of possible correction and the treatment required Relief of pain may be a second objective in these patients

Correction is obtained by traction and lateral bend by which means the turnbuckle cast obtains excellent results Equally good results are obtained by the localizer body cast (fig 5), without the handicaps of the turnbuckle, such as recumbency and hospitalization

---

Consultant, Orthopaedic Hospital, Los Angeles, and St Luke Hospital, Pasadena

Read before the Section on Orthopedic Surgery at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956

Correction with a localizer is obtained by traction, lateral bend, and local posterolateral pressure over the rib angulation At this time the corrective cast is applied (fig 6) The patient is ambulatory immediately, which is a beneficial factor for the patient and economical as well

To maintain correction obtained by the cast, surgical immobilization of the entire area of the curve is necessary Apical rotation and angulation, both of which are characteristics of a curvature, must be included in the fusion area The curve is measured most easily by Ferguson's[1] method of centering the most rotated vertebra at the apex of the curve and then centering the neutral vertebrae that are without rotation or angulation at the ends of the curve The lines connecting these dots will form an angle, which can be read as the degree of curvature The fusion area should include this entire extent of the curve

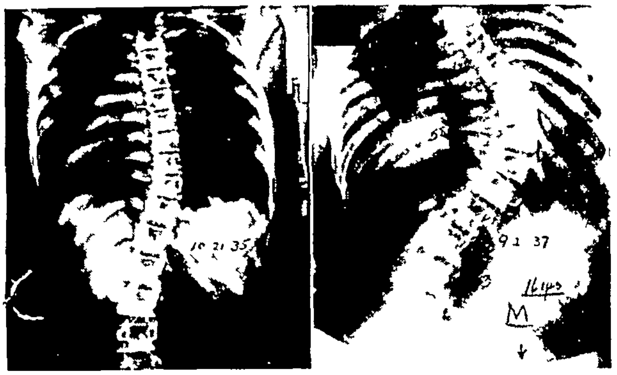

Fig 2—Angulation with little if any rotation in thoracic vertebrae, but angulation and rotation in the lumbar curve in 14-year-old patient Degree of deformity is same Note increase of deformity in two years, during period of rapid vertebral growth

The flexibility or correctibility of a curvature is less with the chronicity of the curve—the older the patient, the higher the curve is in the thoracic area The average amount of correction is about 25 degrees

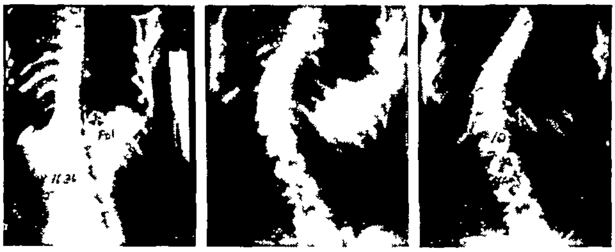

Fig 3—*Left* roentgenogram of patient at 11 years of age who had poliomyelitis at 8 years *center* at 16 years, *right*, at 19 years Note increase in deformity With completion of iliac apophysis, there has been no increase in deformity

Percentagewise the best results are in the smaller curvatures In a 30-degree curve, 25 degrees of correction would result in a residual 5-degree deformity, whereas, in a 50-degree deformity, 25 degrees of correction would result in a 25 degree deformity, which is still quite noticeable and objectionable Correction and fusion should be done on structural deformities when first noticed, particularly if there is much expected vertebral growth Correction should be centered on the most deforming curve, which is commonly the thoracic curve In more severe cases, both thoracic and lumbar curves should be corrected and fused

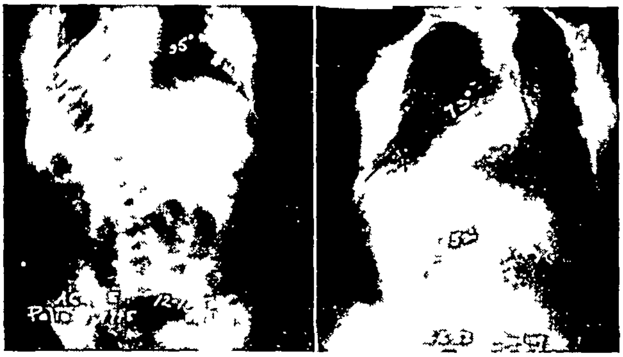

Fig 4—Rapid increase of scoliosis even before period of rapid vertebral growth in patient who had poliomyelitis at 7 years of age This patient had 12 fractures of the long bone prior to her poliomyelitis, indicating a weak bone structure The type of bone will determine the rapidity of increase in scoliosis (*left* aged 8 *right*, aged 10)

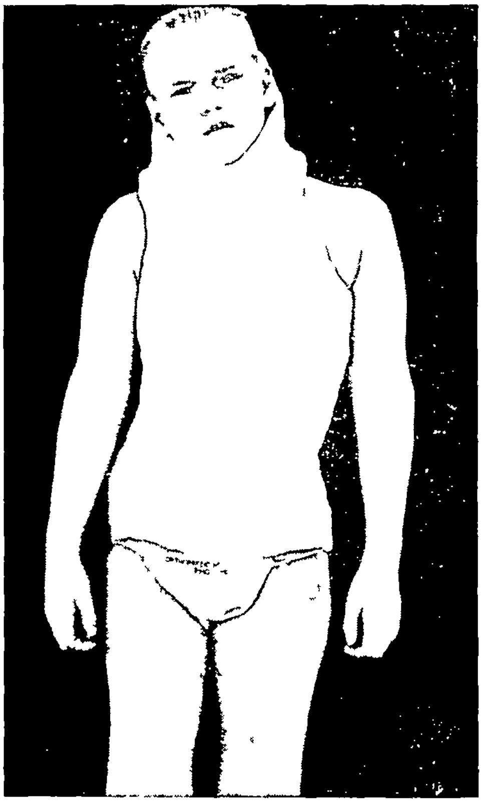

Fig 5—Completed localizer cast Note correction with slight lateral bend in cast Patient is ambulatory

With the localizer cast the patient is ambulatory all the time, except for the 7 to 10 days after surgery Correction is obtained by one or two casts, two to four weeks apart, prior to surgery Surgery is accomplished through a posterior window in the cast or through a bivalved cast One week later a new snug localizer cast is applied Three or four months later the cast is changed and the roentgenograms are taken for check of the fusion area The total postoperative period of immobilization is about 8 to 10 months Roentgenographic examination of the solidity of the fusion is the guide to the removal of the cast

Failures in maintaining correction are due to inadequate length of fusion or inadequate strength of fusion These difficulties can happen to any surgeon and should be suspected in every case Correction of pseudarthrosis should be done when recognized If there is any loss of correction in a deformity, we may readily attribute it to the fact that the fusion is too short or the fusion is not strong enough In the growing child a pseudarthrosis or short fusion can be a cause for increasing deformity In those with completed vertebral growth, there will be a loss of correction comparable to the flexibility in the area involved Pain may or may not be present (fig 7)

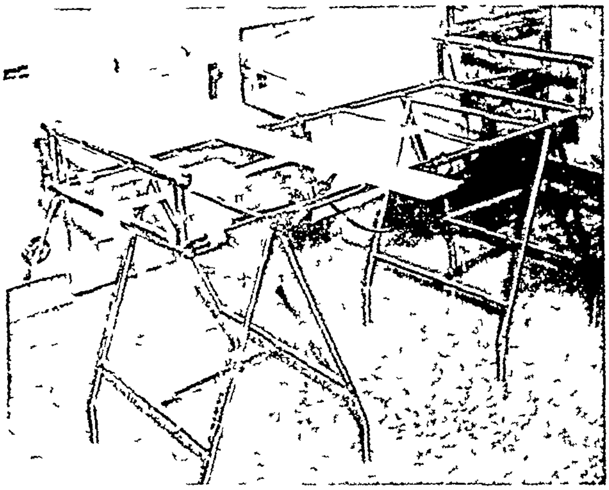

Fig 6 —Scoliosis casting table Note localizer are attached under side bars of table Patient lies supine on pull-out strap while under head and pelvic traction Localizer jack tip directs corrective pressure posterolaterally over the rib angulation

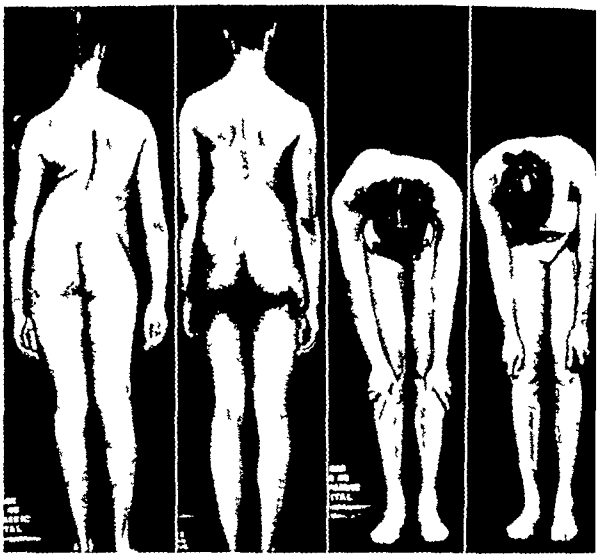

Fig 7 —Rib angulation with bending forward in 14 year-ol girl with severe scoliosis After correction and fusion, note correction of rib angulation bending forward

Diagnosis of Leukemia in Children —When one sees a young child who has anemia, enlargement of the liver, spleen and lymph nodes, purpuric manifestations and an increase in the number of leukocytes and lymphocytes, with or without immaturity in the latter cells, the diagnosis of leukemia must be made with caution because of the pronounced lability of the bone marrow and blood of young children in response to acute and chronic infections, intoxications, malignant lesions and severe hemorrhage By careful and repeated observation of both the peripheral blood and bone marrow, it is usually possible to rule out the diagnosis of leukemia when the child is actually suffering from some other disease By far the largest number [of 44 patients referred to the Mayo Clinic] because of the suspicion that they might have leukemia had acute infections to which their blood reacted by the presence of leukocytosis, lymphocytosis or both Four of the children had pertussis, one of these had a leukocyte count of 130,000 per cubic millimeter of blood, of which 80 per cent were immature lymphocytes This patient was less than a year old, an age when the response of blood to infection may be greatly exaggerated Other children in this group had acute infections of the respiratory, gastrointestinal or urinary tract or other evidence of sepsis Some patients with atypical rheumatic fever or acute exacerbations of rheumatoid arthritis presented difficulties in diagnosis Five children had infectious mononucleosis, which is easily confused with leukemia because of the enlarged liver, spleen and lymph nodes and the increase in lymphocytes in the blood The presence of the atypical lymphocytes associated with infectious mononucleosis and of a high heterophil titer was helpful in the differential diagnosis in these cases —S D Mills, M D , Differential Diagnosis of Acute Leukemia in Children, *The Medical Clinics of North America,* July, 1956

ANESTHESIA FOR SPLENECTOMY IN PATIENTS WITH BLOOD DYSCRASIAS

Robert N. Reynolds, M.D.
and
Benjamin Etsten, M.D., Boston

• *The choice of anesthetics for patients undergoing splenectomy is considered on the basis of experience with 205 patients who had various blood dyscrasias. Congenital spherocytosis was present in 33 patients, and light cyclopropane anesthesia plus administration of tubocurarine, with controlled respiration, was used in 22 of these. It afforded a stable cardiocirculatory state without significant complications either during or after surgery. A second group consisted of 49 patients with acquired hemolytic anemia, a third of 79 with thrombocytopenic purpura, and a fourth of 44 patients with pancytopenia, neutropenia, and aplastic anemia. Complications were most numerous in the purpuric group, in which the splenectomy often failed to have a therapeutic effect, so that there were seven postoperative deaths. It was not found necessary to choose anesthetic agents for the sake of their effects on the contractility of the spleen. The choice was made, rather, on the basis of the patient's liability to hemorrhage and hypotension. Endotracheal and intestinal intubation were avoided whenever the platelet count was low, in order to reduce the danger of bleeding; spinal anesthesia was avoided when the circulating blood volume was low. The policy was to maintain an adequate blood volume with transfusions of fresh, whole blood, but to transfuse cautiously in cases of acquired hemolytic anemia because of the hazard of severe hemolytic reactions.*

Splenectomy for patients with specific types of blood dyscrasias is of therapeutic value, and in many instances the operation is performed in the presence of a reduction of blood cells or platelets or both in spite of intensive preparation.[1] The physiological anesthetic management of patients with hematological disorders requiring an intra-abdominal operation is based upon an understanding of the pathological entities.

The relationship of the splenic functions to the blood dyscrasias has been described by Dameshek, Doan, and others.[2] Dameshek believes that the spleen normally exerts an inhibitory effect on the bone marrow and also has a direct phagocytic effect on the cellular blood elements. The term 'hypersplenism' indicates an accentuation of these functions. When this occurs, phagocytic or hemolytic activity is increased and the escape of the mature cells from the bone marrow is blocked. Either a pancytopenia (total reduction of all cellular elements of the blood) or a selective cytopenia (anemia, thrombocytopenia, or neutropenia) may ensue (table 1). Hypersplenism is classified into two groups: (*a*) primary hypersplenism, a primary or idiopathic disorder of the spleen, and (*b*) secondary hypersplenism, a complication of a coexisting disease. It is also believed that an antigen-antibody reaction plays a part in the destruction of the blood cells in certain cases of hypersplenism[3] and may explain in part the response to the administration of corticotropin (ACTH) and corticosteroids.

The clinical indications for splenectomy are divided into three main groups: (1) the hypersplenic hemolytic anemias, (2) the hypersplenic cytopenias, and (3) splenism. 'Splenism' is a term denoting the inhibitory effect of the normal spleen on the bone marrow. When the bone marrow is hypofunctioning, this normal inhibitory effect of the spleen accentuates the hypoplasia, as, for example, in patients with hypoplastic anemia.

Preoperative Preparation

Although the hematologist is primarily responsible for the clinical preparation of these patients, it is important that the anesthetist and surgeon also share the responsibilities for the preoperative preparation. Either fresh whole blood, fresh polycythemic blood, or packed platelets are given to patients with thrombocytopenic purpura before and during surgery. The bleeding is less when a platelet-rich transfusion is administered during surgery. To avoid disintegration of the platelets, the blood is collected by gravity in plastic containers.

Blood transfusions should be given cautiously to patients with acquired hemolytic anemia because a severe hemolytic reaction may occur. Frequently, the transfused red blood cells hemolyze rapidly. When there is no improvement in the red blood cell count, splenectomy is frequently performed and can serve as a lifesaving procedure.

The administration of corticotropin or corticosteroids such as cortisone, prednisone (Meticorten), or hydrocortisone often will cause a remission in patients with idiopathic thrombocytopenic purpura and acquired hemolytic anemia. In any event, corticotropin or the corticoids are routinely given before surgery because the blood cell or platelet count may increase in many of these patients.

The type and dosage of preoperative hypnotic and sedative medicaments depend on the type of blood dyscrasia, on the patient's age and physical condition, and on the presence or absence of coexisting disease

---

Assistant Professor of Anesthesia, Tufts University School of Medicine, and Anesthetist, New England Center Hospital (Dr. Reynolds), Professor of Anesthesia, Tufts University School of Medicine and Anesthetist-in-Chief, New England Center Hospital (Dr. Etsten).

Read before the Section on Anesthesiology at the 105th Annual Meeting of the American Medical Association, Chicago, June 14, 1956.

Narcotics may cause profound respiratory depression in patients with anemia, and it is therefore advisable to use a barbiturate rather than morphine. Either a barbiturate or morphine may be used safely in patients with thrombocytopenic purpura, because most of these patients have normal hemoglobin values.

TABLE 1.—*Types of Hypersplenism*

Type	Pathology	Clinical Condition
Primary or idiopathic	Deficiency or decrease in circulatory platelets	Idiopathic thrombocytopenic purpura
	Deficiency or decrease in circulatory red blood cells	Hereditary hemolytic anemia (spherocytosis) Acquired hemolytic anemia
	Deficiency or decrease in circulatory neutrophils	Splenic neutropenia
	Deficiency or decrease in all three elements	Splenic pancytopenia
Secondary	Deficiency of any one or combination of the cellular elements in blood secondary to known disease (Boeck's sarcoid, leukemia, portal hypertension due to Hodgkin's disease, nonpyogenic infectious states causing splenomegaly)	Secondary thrombocytopenic purpura Acquired hemolytic anemia Neutropenia Pancytopenia

Anesthetic Agent and Technique

The choice of the anesthetic agent and technique depends upon the type of blood dyscrasia and the surgical approach. There are three generally accepted approaches for the surgical removal of the spleen: transthoracic, thoracoabdominal, and abdominal. One observer believes that the abdominal approach is preferable to the transthoracic route and that exploration of the abdomen is an important part of a celiotomy for splenectomy.[1a] Frequently, patients with hereditary spherocytosis have cholelithiasis, and, when this occurs, cholecystectomy is performed in addition to splenectomy.

Complete abdominal muscular relaxation is essential to facilitate the surgical removal of the spleen via the intra-abdominal route. Other factors of equal importance are minimal movements of the diaphragm and the viscera necessary to permit a careful dissection of the spleen from its attachments. These conditions are achieved by the administration of a muscle relaxant during light levels of general anesthesia. Whenever the muscle relaxants are administered, we believe it is essential that the patient's respirations be either controlled or assisted by the anesthetist to avoid respiratory acidosis. Controlled respiration is preferred because by this method the diaphragm rises and becomes motionless, the spleen is visualized easily, and a quiet surgical field is obtained. Depression of the vasomotor center and the peripheral circulatory mechanisms usually does not occur when the anesthesia is light.

TABLE 2.—*Number of Patients in Each Hemoglobin-Value Group by Clinical Diagnosis*

	Gm. of Hemoglobin/100 Cc. of Blood		
Diagnosis	6-9	9.1-12	12.1-15
Hereditary spherocytosis		28	5
Acquired hemolytic anemia	17	29	3
Idiopathic thrombocytopenic purpura	5	26	32
Secondary thrombocytopenic purpura	2	10	4
Pancytopenia (primary and secondary)	3	9	7
Neutropenia (primary and secondary)	1	6	5
Hypoplastic anemia	3	10	
Total	31	118	56

Some observers state that the use of ether may be beneficial because it contracts the spleen and expels blood into the systemic circulation.[4] This phenomenon is presumed to occur via the stimulation of the sympathetic nervous system.[5] It has also been stated that thiopental sodium, cyclopropane,[5] and spinal anesthetics[6] cause the spleen to enlarge. These findings were based on observation of the effects of various anesthetic agents on the dog's spleen. The dog's spleen has a well-developed smooth muscle capsule with a strong contractile power, as opposed to the human spleen, which has few muscle fibers in the capsule.[7] It is, therefore, questionable whether anesthetic agents can significantly contract the normal-sized human spleen. In patients with long-standing enlargement of the spleen associated with hereditary spherocytosis, it has been noted that the spleen does not contract after the injection of epinephrine.[8] On the other hand, epinephrine and presumably ether will contract the enlarged spleen in patients with pancytopenia and neutropenia. Although this may occur, we believe that the choice of an anesthetic agent should not be based solely on the fact that its contractile effect on the spleen increases the red blood cell count and blood volume with abnormal blood. An adequate circulating blood volume can be easily maintained with fresh whole blood transfusions.

TABLE 3.—*Number of Patients by Clinical Diagnosis, in Whom Each Anesthetic Technique Was Used*

	Inhalation		
Diagnosis	Intubation*	Without Intubation†	Spinal‡
Hereditary spherocytosis	21	10	2
Acquired hemolytic anemia	42	6	1
Idiopathic thrombocytopenia purpura	2	23	38
Secondary thrombocytopenic purpura	8	4	4
Pancytopenia	12	3	4
Neutropenia	11	1	
Hypoplastic anemia	5	4	4
Total	101	51	53

* Respiration controlled.
† Respiration assisted or spontaneous.
‡ With supplementary intravenous and/or inhalation anesthesia.

It has been observed that cyclopropane depresses the circulation less than other agents used in inhalation anesthesia.[9] It has also been shown that it exerts a pressor-like effect on the peripheral vascular bed[10] and aids in sustaining an effective blood pressure in the presence of surgical blood loss.[11] In view of these observations it is apparent that the choice of an anesthetic agent should be based on its effect on the circulation rather than on its effect upon the spleen. Cyclopropane and other agents do not significantly affect the bleeding and clotting time of blood.[12] An increase in oozing from the blood vessels during surgical anesthesia may be due to carbon dioxide retention.[13]

Usually there are exacerbations and remissions in the course of thrombocytopenic purpura. Although splenectomy is elective in most instances and is performed during a remission, the platelet count is usually less than normal. In other instances, the operative procedure is performed during an acute episode to prevent intracranial hemorrhage or exsanguination The choice of the anesthetic technique is particularly important because of the low platelet count and prolonged bleeding time We feel that endotracheal intubation is contraindicated in patients with thrombocytopenic purpura because it might cause excessive hemorrhage in the tracheobronchial mucosa

Some observers believe that a spinal anesthetic should not be given to patients with prolonged clotting time because of the danger of subarachnoid hemorrhage [14] The clotting time in patients with thrombocytopenic purpura is usually normal, the bleeding time is prolonged We have, however, seen no complications due to hemorrhage in subarachnoid or epidural spaces Since most all of these patients have normal blood volumes and near normal hemoglobin values, spinal anesthesia supplemented with light cyclopropane anesthesia is preferable to deep inhalation anesthesia Assisted or controlled respiration is usually necessary during deep anesthesia When this is done without the use of an endotracheal tube, acute distention of the stomach may occur Spinal anesthesia should not be used during an acute exacerbation of the disease when the patient is hemorrhaging and has a low hemoglobin value and a low circulating blood volume When this occurs, light cyclopropane anesthesia supplemented with small doses of muscle relaxants is used without an oropharyngeal airway or endotracheal tube

Material and Results

From 1950 to 1955, 205 patients with hematological disorders were anesthetized for splenectomy For purposes of analysis, the patients were classified according to the clinical diagnosis

TABLE 4 —*Number of Patients, by Clinical Diagnosis, Undergoing Anesthesia with Various Agents*

Diagnosis	Cyclo propane Tubo curarine Chloride	Ethyl Ether with Nitrous Oxide or Vinyl Ether	Thiopental Sodium Nitrous Oxide Tubo curarine	Tetra caine Hydro chloride Cyclo propane
Hereditary spherocytosis	22	8	1	2
Acquired Hemolytic anemia (primary and secondary)	41	5	2	1
Idiopathic thrombocytopenic purpura	16	8	1	38
Secondary thrombocytopenic purpura	9	2	1	4
Pancytopenia (primary and secondary)	10	3	2	4
Neutropenia (primary and secondary)	11		1	
Hypoplastic anemia	7	2	0	4
Total	116	28	8	53

Hereditary Spherocytosis—There were 33 patients with hereditary spherocytosis, with an average age of 18 years Three patients were over 40, and 16 were under 20 years of age The hemoglobin values ranged from 9 5 to 16 Gm per 100 cc of blood (table 2) The anemia was not as severe as that observed in patients with acquired hemolytic anemia

Cyclopropane plus tubocurarine chloride was used in 22 patients, spinal anesthesia in 2 patients, ether in 8 patients, and thiopental–nitrous oxide–curare in one patient (tables 3 and 4) It was observed that a stable cardiocirculatory state was maintained when there was light cyclopropane anesthesia plus administration of tubocurarine, with controlled respirations There were no significant complications either during or after surgery (table 5)

Acquired Hemolytic Anemia—Splenectomy was performed on 49 patients with acquired hemolytic anemia, primary in 27 and secondary in 22 The average age was 42 years (range 8 months to 77 years) Six patients of this group of 49 had pulmonary disease consisting of either bronchitis or pulmonary emphysema and 16 had cardiocirculatory disease diagnosed as coronary artery disease and arteriosclerotic heart disease

TABLE 5 —*Number of Patients, by Clinical Diagnosis, with Various Nonfatal Postoperative Complications*

Diagnosis	Ate lectasis	Pneu monia	Pul monary Embolus	Myo cardial Infarc tion	Cerebral Vascular Accident	Spinal Headache
Hereditary spherocytosis						
Acquired hemolytic anemia (primary and secondary)		1	1			
Thrombocytopenic purpura (primary and secondary)	3	2	1	1	2	3
Pancytopenia						
Neutropenia						
Hypoplastic anemia						1
Total	3	3	2	1	2	4

The average preoperative hemoglobin value per 100 cc of blood was 9 7 Gm (range 6 4 to 12 7 Gm) (table 2) In 7 of the 49 patients the hemoglobin value was less than 8 Gm per 100 cc Transfusions of packed red blood cells were given primarily to increase the red blood cell count without increasing the total blood volume In seven patients washed red blood cells were administered to avoid reactions related to the plasma constituents Six patients demonstrated cold agglutinins in their blood, and they were given transfusions of warmed blood

Endotracheal cyclopropane-curare anesthesia, with controlled respirations, was administered in 41 of the 49 patients Ether was used in five patients, thiopental–nitrous oxide–curare in two patients, and spinal anesthesia in one patient (tables 3 and 4) Systemic arterial hypotension (a fall in systolic blood pressure of more than 25%) was associated only with excessive blood loss or deep levels of anesthesia The periods of hypotension in all instances were transient, a prompt pressure response occurred after adequate blood replacement or after lightening the levels of anesthesia Manual control of respiration during surgery did not apparently cause any change in the blood pressure even in instances of sudden hemorrhage or undue depths of anesthesia Bronchospasm occurred in three patients, and this complication was relieved by the intravenous administration of small amounts of succinylcholine

Two patients in this group had major postoperative complications one had a nonfatal pulmonary infarct and one had pneumonia (table 5) There was one postoperative death 30 days after splenectomy, due to a continuation of the hemolytic anemia

Thrombocytopenic Purpura —Splenectomy was performed on 79 patients with a diagnosis of thrombocytopenic purpura Of this group, 63 patients, with an average age of 28 years, had primary disease and 16, with an average age of 41 years, had secondary disease

Primary Thrombocytopenic Purpura The patients with idiopathic or primary thrombocytopenic purpura had an average platelet count of 53,200 per cubic millimeter (range 51,200 to 306,000) Endotracheal and intestinal intubation were not performed whenever the platelet count was less than 100,000 because of the danger of initiating pharyngeal, laryngeal, or tracheal hemorrhage However, endotracheal intubation was performed in two patients who responded to steroid therapy with a normal platelet count and bleeding time

Ten patients had hemoglobin values less than 10 Gm per 100 cc of blood, and the combination of anemia and thrombocytopenia presented a difficult anesthetic problem These patients were anesthetized with cyclopropane by mask to-and-fro absorption technique plus minimal amounts of tubocurarine Spinal anesthesia was not used because of the decreased circulatory blood volume, and endotracheal technique was avoided because of the increased bleeding time Fifty three of the patients had normal hemoglobin values Thirty-eight of these were given spinal plus light cyclopropane anesthesia Inhalation anesthesia was used to prevent reflex retching or perception of pain associated with traction on the splenic pedicle Five of the patients who were under 10 years of age were anesthetized with cyclopropane and a muscle relaxant Open-drop ether was used in eight children and infants whose ages were under 5 years (range 6 weeks to 5 years)

Secondary Thrombocytopenic Purpura Of the 16 patients with secondary thrombocytopenia, 8 had platelet counts ranging between 100,000 and 200,000 per cubic millimeter and received endotracheal inhalation anesthesia Four patients with low platelet counts and normal hemoglobin values received spinal anesthesia Two patients received inhalation anesthesia without intubation because the platelet count was less than 50,000 per cubic millimeter and the hemoglobin level was less than 9 Gm per 100 cc Two infants received ether by open-drop technique

Headaches occurred in three patients, and there were no other postoperative complications associated with spinal anesthesia Blood was aspirated from the subarachnoid space following a lumbar puncture in 1 out of 42 patients who received spinal anesthetics, and no neurological sequela occurred There were five patients who had postoperative pulmonary complications, three with atelectasis and two with pneumonia Endotracheal suction had not been used in these patients because of a poor platelet response after splenectomy and the danger of causing tracheal hemorrhagic edema One patient developed a myocardial infarction on the third postoperative day and recovered The response of platelet formation immediately after splenectomy is often exaggerated, and the platelet count may rise to over a million This may be a factor in the occurrence of a coronary thrombosis

There were seven postoperative deaths Splenectomy did not produce a therapeutic effect in these patients, the platelet count remained low and bleeding continued In two of these patients cerebral hemorrhage was the cause of death In the other four the cause of death was prolonged hemorrhage into either the gastrointestinal tract or the thoracic, ab dominal, or uterine cavity as well as at the site of surgery It was of interest to find tracheobronchial hemorrhage during postmortem examination in one of these patients who had received spinal anesthesia

Pancytopenia, Neutropenia, and Aplastic Anemia —There were 44 patients with a diagnosis of pancyto penia, neutropenia, or aplastic anemia Nineteen patients with pancytopenia (primary in 10, secondary in 9) had an average hemoglobin level of 10 Gm per 100 cc and an average platelet count of 122,000 per cubic millimeter Twelve patients with neutropenia (primary in 9, secondary in 3) had normal hemoglobin and platelet values prior to surgery Thirteen patients with hypoplastic anemia had an average hemoglobin value of 10 8 Gm per 100 cc and an average platelet count of 202,000 per cubic millimeter Tables 3 and 4 show the techniques and agents used in this group of patients The use of inhalation anesthesia with or without endotracheal intubation and of spinal anesthesia was dependent upon the platelet count, hemoglobin value, and circulating blood volume There were no major postoperative complications in this group

Summary and Conclusions

A series of 205 patients with blood dyscrasias underwent splenectomy The presence of severe anemia, prolonged bleeding time, or decreased circulating blood volume are the major factors to be considered in the selection of the anesthetic technique and agent It appears more reasonable to choose an agent on the basis of these factors than on the basis of its effect on the spleen Contraction of the spleen in patients with blood dyscrasias may introduce abnormal blood elements into the general circulation It is preferable to maintain an adequate circulating blood volume with fresh whole blood transfusions

171 Harrison Ave (11) (Dr Reynolds)

Dr William Dameshek gave permission to report the patients in this series

CLINICAL EXPERIENCES AND STUDIES IN CURLING'S ULCER

Capt Robert P Hummel (MC), 1st Lieut Gerard F Lanchantin (MSC)
and
Lieut Col Curtis P Artz (MC), U S Army

• *Evidence of gastrointestinal (usually duodenal) ulceration was seen in 20 out of 1,000 patients hospitalized for burns over a period of 78 months The ulceration was found at autopsy in 17 of the 80 patients who died it was accepted as the immediate cause of death in 4 The concentration of uropepsin in the urine was higher in the patients with the more severe burns, and this was associated with high concentrations of pepsin and hydrochloric acid in the gastric juice*

Weigel and co-workers,[1] in a survey of the literature beginning with the first reports by Swan and Curling and continuing to January, 1953, found a total of 139 cases of gastrointestinal ulceration after burns Woldman [2] analyzed the results of 943 consecutive autopsies and reported three cases of acute ulceration of the upper gastrointestinal tract in six cases of severe burns In 1953, Bothe and Magee [3] reported an additional case of multiple Curling's ulcers of the esophagus, stomach, and duodenum in a 68-year-old woman who had a burn covering 25% of the body surface

The development of gastrointestinal ulceration after thermal injury is a serious complication that has been seen with increasing frequency since the establishment of the burn division of the surgical research unit, Brooke Army Medical Center A review of the experience with Curling's ulcer at this unit and of a series of gastric studies performed on burned patients forms the basis of the present report

Clinical Experience with Twenty Cases

Incidence—During the period of six and one-half years from December, 1949, through May, 1956, 1,000 burned patients have been hospitalized at Brooke Army Hospital The total number of deaths among these patients was 80 during this same period Gastrointestinal ulceration was found in 17 of the 80 patients who died Three patients survived who were thought to have had Curling's ulcer (table 1) From December, 1949, to January, 1953, only 20 patients died The five cases of Curling's ulcer that occurred among these 20 patients were reported by Weigel and co-workers [1] in 1953 (cases 1 through 5, table 1) Because the burns treated by the surgical research unit have increased in severity since 1953, the number of deaths per year has increased since that date, as have the number of patients with Curling's ulcer However, the incidence of gastrointestinal ulceration after thermal injury found at autopsy at this unit (21%) remains approximately the same as that reported by Weigel and co-workers (25%)

The incidence of gastrointestinal ulceration among all burned patients admitted to Brooke Army Hospital over the period of six and one-half years was 2% (a total of 1,000 patients of whom 20 had ulcers) Although the incidence of 21% found at autopsy is unquestionable, the over-all incidence of 2% is probably lower than the actual occurrence Patients in this series were considered to have recovered from Curling's ulcer only if the massive hemorrhages in the upper part of the gastrointestinal tract responded to the administration of 2,000 to 3,000 cc of blood during a 12-hour to a 24-hour period Other patients may well have had gastrointestinal ulceration Drainage through a gastric suction tube showed the presence of bright red blood in several patients, and others complained of abdominal pain When these patients were treated medically, their symptoms subsided

Extent of Burn—The distribution of age and sex of the patients who developed Curling's ulcer corresponds roughly to the normal composition of the patient population in the burn ward In general, the patients with extensive burns were the ones who developed gastrointestinal ulceration Three patients with less severe burns also developed Curling's ulcer (cases 8, 18, and 19) In each case, however, these smaller burns were accompanied by an added insult, the

---

From the Surgical Research Unit, Brooke Army Medical Center, Fort Sam Houston Texas patient in case 18 had an open fracture of T-12 with paralysis, while the patients in cases 8 and 19 had septicemia as a complication The average percentage of the body surface burned in the 20 patients who developed Curling's ulcer was 61%, including a third-degree involvement of 42% Considering only those patients who died, the average total involvement was 64%, with a third-degree involvement of 45% The three patients who survived had an average of 43 3% of the body surface burned, with 25% being third-degree burns

Symptoms—Seven patients in this series had no signs or symptoms of upper gastrointestinal ulceration, although the lesions were found at autopsy Two patients (cases 8 and 14) had abdominal complaints compatible with the presence of a penetrating peptic ulcer One patient (case 6) developed a rigid abdomen, although his ulceration did not penetrate through the submucosa of the duodenum Acute hemorrhage was the first sign of pathology in 10 instances These patients were without recognizable prodromal symptoms The day of hemorrhage varied from the 2nd postburn day to the 48th however the hemorrhage generally occurred within the first three weeks after thermal injury, with the average being 18 5 days after injury Perforation occurred only twice (cases 2 and 8) The exact date of perforation is not known in these two patients, but it was probably sometime during the second month after injury In both instances the perforation was fatal Two patients had ulcers that penetrated into the pancreas (cases 7 and 14)

Location of Ulcer—The location of the ulceration in most of the patients in this series was in the duodenum In nine cases the duodenum alone was involved, while both the duodenum and stomach were ulcerated in three patients In three cases there were ulcerations in the stomach alone, and in one patient the duodenum and jejunum were ulcerated The exact site of the ulceration was unknown in four cases These included three patients who lived and one patient on whom an autopsy could not be obtained Multiple ulcerations were found at autopsy in seven patients The other autopsies revealed only one ulcer present either in the duodenum or stomach or in both organs

Treatment—The seven asymptomatic patients received no specific therapy for ulcers Of the 10 patients who had acute hemorrhage, all were treated with an intensive program of blood replacement and with administration of antiulcer medicaments, such as aluminum hydroxide (Amphojel) and methantheline (Banthine) bromide In two of the patients with bleeding peptic ulcers (cases 16 and 17), subtotal gastric resections were performed when blood replacement failed to keep pace with blood loss In both patients, all incisions showed complete inability to heal, although the ulcers were eliminated and the hemorrhage was controlled by the operation

Three patients survived (cases 18, 19, and 30) Gastrointestinal bleeding was present in each case, but it subsided within 24 to 48 hours All three patients were treated with an intensive program of blood replacement Each of them received more than 3,000 cc of whole blood over a period of 24 to 36 hours Methantheline bromide and aluminum hydroxide were also given In the three cases in which abdominal pain or rigidity was the only symptom or sign of the presence of peptic ulceration (cases 6, 8, and 14), aluminum hydroxide and methantheline bromide were given without obvious benefit

TABLE 1—*Summary of Data on Twenty Cases of Curling's Ulcer*

Case No	Age Yr	Sex	% of Body Surface Burned: Total	% of Body Surface Burned: Third Degree Burn	Ulceration: Location	Ulceration: Type	Hemorrhage on Postburn Day	Cause of Death	Death on Postburn Day	Remarks
1*	23	M	45	[illegible]	Duodenum	Multiple	10	Hemorrhage	13	Cortisone given for first 3 days

18	37	M	23	17	Unknown		16			Open fracture of T 12 with paralysis given 3 000 cc of blood
19	22	M	35	15	Unknown		12			Given 3 000 cc of blood in 12 hr septicemia
20	21	M	72	43	Unknown		23			Given 3 500 cc of blood in 24 hr septicemia
Averages			61	42			18 5		23	

* Cases previously reported by Weigel and co workers[1]

Causes of Death—In only four patients was the gastrointestinal ulceration considered the immediate cause of death The patients in cases 1 and 11 died from hemorrhage and the patients in cases 2 and 14 from peritonitis after perforation In the other 15 cases, the patients either survived or died from other causes Septicemia was present in 13 patients, and in 10 it was considered to be the primary cause of death

Clinical Studies

There are numerous theories as to the cause of gastrointestinal ulceration after cutaneous burns These theories were reviewed extensively in 1938 by Harkins[4] and in 1950 by Friesen[5] The most commonly proposed theories are that Curling s ulcer is related in some way to sepsis,[6] to hemoconcentration in the wall of the stomach and duodenum,[7] and to failure[2] or hyperactivity[7] of the adrenal glands It has been demonstrated that there is an increased level of blood histamine present in burned animals,[8] but these experiments gave no evidence that the elevated levels of blood histamine played any role in the formation of Curling s ulcer In a small series of dogs, it was reported that gastric secretions and acidity increased after a burn[9]

Gray and co-workers[10] and other independent workers[11] noted that an accurate estimate of the peptic activity of the stomach could be obtained by analyzing the urine for the level of uropepsin, and they observed that the level of this enzyme was elevated in patients with duodenal ulcer, as opposed to normal individuals The same investigators also observed that the excretion of uropepsin was increased by adrenal and pituitary hyperactivity, "stress response,' and corticotropin and cortisone therapy Only Gray and co-workers[12] reported an instance of uropepsin studies performed on a burned patient These studies were performed on a patient with an undisclosed amount of second-degree burn who showed elevated levels of uropepsin at the end of the first postburn week No studies have been reported on the gastric contents of burned patients

It was decided to study a series of hospitalized patients with burns to determine whether the peptic activity or the level of gastric acidity varied with the extent of burn and also whether they were related in any way to the development of Curling s ulcer

Uropepsin Studies—Twenty-six moderately to severely burned patients were studied Serial analyses were performed for the levels of uropepsin and the gastric contents examined for the presence of acid and blood Eosinophil counts were also performed

Experimental Methods Urine was collected over a 24-hour period and placed under refrigeration until analysis The potential pepsin activity of the urine (uropepsinogen level) was measured by the method described by Bucher[13] The method used involved the following procedure an aliquot from a 24-hour collection of urine was acidified to convert pepsinogen to pepsin Pepsin activity was measured by the incubation of an aliquot of the diluted, acidified urine with a hemoglobin substrate at 37 5 C, pH 1 75 to 2 0, for 60 minutes The phenolic compounds released by the proteolysis of hemoglobin were measured by the Folin-Ciocalteau phenol reagent in the filtrate obtained after the undigested hemoglobin was precipitated by trichloroacetic acid A tube, containing the same reagents but to which trichloroacetic acid had been added to stop the reaction before incubation, was used to account for the nonprecipitable phenolic compounds normally present in urine The blue color formed by the Folin-Ciocalteau reaction was then measured at 540 mμ in a Coleman junior spectrophotometer and equated to a standard tyrosine solution

Pepsin activity was expressed in terms of the difference between the incubated and unincubated samples (blank) as milligrams of tyrosine released per milliliter of urine Replicate determinations on the same specimens of urine indicated that the method had a reproducibility in the order of 8% Serial dilution of the same specimen of urine indicated pepsin activity to have a linear correlation with urine concentration Bucher s average normal value was approximately 300 mg per 24 hours, with a range of 35 to 875 mg per 24 hours The five normal levels obtained in this laboratory averaged 200 mg of tyrosine per 24-hour urine volume

* Burns in group A include those covering 30% or less of the body surface burns in group B include those covering more than 30% of the body surface

† Patient died

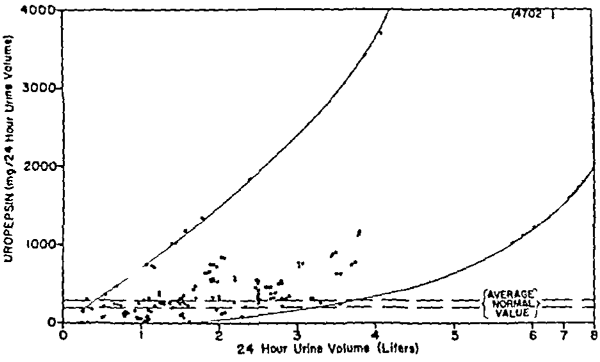
‡ Uropepsin level after the administration of cortisone

§ Patient had Curling s ulcer

Results of Uropepsin Studies Table 2 lists the highest uropepsin output for each patient studied, both in milligrams per 24 hours and in milligrams per milliliter The patients were divided into two groups, depending upon the percentage of total burn Group A consisted of patients with burns involving up to and including 30% of the total body surface, while group B included patients with burns involving more than 30% In the patients with the less severe burns (group

A), uropepsin excretion was at a normal or high-normal level unless some added systemic insult was present The patient in case 26 had septicemia and the patient in case 30 had a deep burn from white phosphorus These were the only two patients in the entire series who were emotionally disturbed enough to require psychiatric consultation

In the group with severe burns (group B), the level of uropepsin excretion was considerably elevated except in a few instances The patient in case 37 had an adrenal insufficiency When cortisone was given, the uropepsin level rose from 0 07 mg to 0 49 mg per milliliter The patient in case 10 was not admitted until 14 days after injury, hence the uropepsin levels prior to admission were unknown The patients in in cases 41 and 12 had renal impairment with rising levels of nonprotein nitrogen It was felt that the lack of elevation in the uropepsin levels in these two cases was due to diminished renal function rather than to failure of the gastric glands to secrete pepsin The level of uropepsin in a 24-hour urine specimen seemed related in some way to the volume of the specimen (see figure)



Graph showing relation of urinary volume to level of uropepsin in 30 burned patients

In patients with primarily second degree burns, uropepsin output seemed to reach a peak during the first and second postburn weeks These levels usually returned to normal by the end of the third week, at which time the burn wounds had healed Patients with third-degree burns tended to have a greater output of uropepsin during their second, third, and fourth postburn weeks, when sloughing occurred in the third-degree wound and considerable infection was present In many of these patients there were elevated uropepsin levels for some time after grafting was performed

Results of Related Studies. Table 2 records the highest level of gastric acid for each patient There was a considerable variability in gastric acidity, although there was a trend toward consistently higher gastric acidities in the severely burned patients (table 2, group B) In all patients the gastric secretions were tested for the presence of blood A trace to a strongly positive reaction was found in all patients in whom a benzidine test was performed

Eosinophil counts generally remained low during the first postburn week, but they began to return to normal during the second and third postburn weeks in all patients studied, unless severe infection was present There seemed to be no consistent relationship between the eosinophil count and the excretion of uropepsin

Relation to Curlings Ulcer Five patients in group B (table 2) developed Curlings ulcer Two of these patients (cases 11 and 12) had the highest concentrations of uropepsin per milliliter, although only the patients in cases 11 and 14 had markedly elevated uropepsin levels per 24 hours As has been stated previously, the patient in case 10 was not admitted until 14 days after her injury, and her early levels of uropepsin were unknown The patient in case 12 had marked renal impairment that may have accounted for the low urinary pepsin level At times, all five patients had at least moderately elevated gastric acidity At other times, gastric analyses were within normal limits

Gastric Pepsin Studies—Since some investigators[14] have stated that they were in doubt concerning the relationship between uropepsin excretion and the actual level of gastric pepsin under conditions of stress and because of the fact that several severely burned patients in the previous study had rather low levels of uropepsin, it was decided to analyze the simultaneous levels of gastric pepsin and uropepsin in a second group of patients

Methods In the preliminary phases of this study, gastric pepsin level was measured by the method of Glass, Pugh, and Wolf[15] This procedure required a somewhat empirical dilution of 1 200 of filtered gastric juice before analysis in order to reduce the pepsin activity to a measurable range and to obviate the effect of a pepsin inhibitor However, marked differences in peptic activity were found, depending upon the dilution employed The greater the dilution of gastric juice, the greater the increase in pepsin activity when peptic activity is calculated on the basis of milliliters of original gastric juice This phenomenon is the result of a disruption of an enzyme-inhibitor complex by means of dilution

In many cases, it was apparent that a 1 200 dilution gave an inaccurate picture of the maximum peptic activity that could be obtained from the gastric specimen To circumvent this problem, it was decided to make a routine assay of each specimen of gastric juice, using a series of five dilutions With this method it was possible to express gastric pepsin activity as a function of the peak activity in the five diluted specimens Although this method of assay assumes constant inhibitor activity in gastric juice, it was considered the only feasible means of assessing gastric pepsin activity without additional chemical fractionation of the specimen

Results Ten patients were included in this study Nineteen simultaneous collections of uropepsin and gastric pepsin were made Urinary corticoids were measured in the same samples of urine upon which the determination of uropepsin was performed (table 3) Both the uropepsin values in milligrams per 12-hour collection period and the concentration of uropepsin are listed and compared with the milligrams per 12-hour gastric collection and the concentration in the gastric contents collected

It has been stated that 1% of the pepsin formed in the gastric glands is secreted in the urine and 99% n the gastric contents [11a] In this series of studies, he relationship between gastric and urinary pepsin alues in 12-hour specimens is much less apparent han that between the concentrations of gastric pepsin and of uropepsin in milligrams per milliliter Variaion between 12-hour urinary and gastric specimens nay well be due to the inability of the gastric suction ube to collect the same percentage of gastric secreions on every occasion The concentration of uropepsin (milligrams per milliliter) in all but one nstance (case 44, table 3) was almost exactly 1% of the concentration of gastric pepsin

It was found at autopsy that one patient in this group (case 15) had Curling's ulcer Studies showed irly high levels of uropepsin per 12-hour period and lso elevated gastric pepsin levels during the same nterval There was a marked increase in the levels of gastric pepsin and urinary pepsin, in gastric acidity, and in excretion of urinary corticoids over the period from the 6th to 13th postburn days During this time, sepsis had increased in the patient This patient had the highest level of urinary corticoid excretion in the entire group

Porter and Silber s method was employed to determine the levels of 11-oxycorticoids present in the urine [16] *In general, the levels of urinary corticoid* excretion corresponded to the total uropepsin output, corticoid excretion was normal with normal levels of uropepsin and elevated when the uropepsin excretion was above average

Comment

Although the over-all incidence of Curling s ulcer among 1,000 burned patients was only 2%, it was a frequent complication among the more severely burned patients From the studies performed, it appeared that the more severely burned patients, that is, those with more than 35% of the body surface burned, and those having smaller burns with added injury or complications had elevated uropepsin excretion and a trend toward higher gastric acidity The levels of uropepsin in these patients seem to be related in some way to renal volume Extensively burned patients with terminal renal failure excreted smaller volumes of uropepsin Burned patients with large urine volumes excreted high levels of uropepsin Generally, the more severely burned patients received more fluid therapy and had higher urinary volumes It must be noted, however, that the concentration of uropepsin per milliliter was higher in the more extensively burned patients

Although the levels of uropepsin and the gastric acidity were elevated in severely burned patients, the levels were of no diagnostic value in determining which patients would develop Curling's ulcer The five patients who developed gastrointestinal ulceration after burns had elevated gastric acidity and elevated excretion of uropepsin, except one patient in whom renal failure was present and another in whom the levels of uropepsin were unknown for the first two postburn weeks Other patients failed to develop Curling s ulcer although they also had high levels of uropepsin and elevated gastric acidity

Diagnosis of gastrointestinal ulceration after burns was not made before the patients developed acute gastrointestinal hemorrhage or had marked epigastric pain Perhaps other patients would have revealed abdominal symptoms had they been more carefully questioned Minor complaints of this nature are often overlooked while attention is given to caring for the more obvious needs of a severely burned patient

Prophylactic treatment of all severely burned patients with aluminum hydroxide or a similar drug is recommended The use of methantheline bromide should be reserved for the onset of symptoms suggestive of gastrointestinal ulceration If hemorrhage occurs, the patient should be treated judiciously with the administration of blood, methantheline bromide, and antacids Gastrectomy should not be considered unless the magnitude of the hemorrhage is so great

† Patient died
‡ Curling s ulcer

that operation is mandatory as a lifesaving procedure In this series, the two patients upon whom gastric resection was performed died There was complete failure of all incisions to heal Both of these patients were extensively burned In each instance, local and systemic infection was present, and the patient's blood metabolites were depleted The cause of the failure of incisions to heal has not been determined However, this emphasizes the importance of conservative treatment in the management of a patient with a bleeding Curling's ulcer

Should operation be necessary because of the occurrence of uncontrollable hemorrhage, it appears that the procedure of choice would be exteriorization of the stomach, with duodenostomy and a jejunostomy and insertion of a catheter for feeding purposes This type of operation might eliminate the complications that follow leakage from sites of anastomosis

Summary

Of 1 000 burned patients admitted to Brooke Army Hospital over a period of six and one-half years, 20 developed Curling's ulcer Of the 80 burned patients who died during this period, 17 (21%) had gastrointestinal ulceration Three patients with gastrointestinal ulceration survived Seven patients were asymptomatic Hemorrhage occurred in 10 instances, and three patients had abdominal pain The majority of the ulcers occurred in the duodenum In only seven instances were the ulcerations multiple Eighteen patients were treated medically Three of these survived Two patients had subtotal gastrectomy, and both died In only four instances was the ulceration thought to be the immediate cause of death

Of 26 burned patients studied for levels of uropepsin and gastric acidity, uropepsin levels were elevated in almost every patient with 35% or more of the body surface burned Gastric acidity was extremely variable but tended to be higher in the more severely burned patients Elevated uropepsin levels and gastric acidity were of no diagnostic value in predicting which patients would develop Curling's ulcer The uropepsin concentration was approximately 1% of the gastric pepsin concentration, when the two were tested simultaneously

It is suggested that extensively burned patients be given antacids prophylactically Conservative medical management is recommended for patients with bleeding Curling's ulcer unless operation is absolutely necessary as a lifesaving procedure

Renewal of Cells —Mitotic figures are often present in adult tissues Undoubtedly, some of this mitotic activity accounts for the slight tissue growth which exists in the adult phase of life However, in a number of locations, the frequency of mitosis greatly exceeds that required for growth Some of the areas of proliferation are easily accounted for, for example, the mitosis in the hair follicle assure the continued elongation of the hair shaft Similarly, the periodic outbursts of mitosis occurring in the ovarian follicles testify to their periodic development In both of these instances there is a structural addition to the tissue, that is, longer hair and new follicles In other cases, however, the tissue in which mitosis takes place shows no change in the number or size of its component structure, and, therefore, the cell production must be balanced by a cell loss In such an instance, the cells of the tissue are said to undergo 'renewal"—C P Leblond and B E Walker, Renewal of Cell Populations, *Physiological Reviews*, April, 1956

SURGICAL CONSIDERATIONS IN TREATMENT OF ESOPHAGEAL HIATAL HERNIA

Theodore T Myre, M D, John W Kirklin, M D, Howard A Andersen, M D
and
O Theron Clagett, M D, Rochester, Minn

• *Operations to correct esophageal hiatal hernia were done in 113 patients Symptoms ascribed to it were present before operation in 78% of the patients, and there had been gastrointestinal bleeding in 19% The hernia proved to be of the sliding type in 97 patients and of the paraesophageal (rolling) type in 16 Surgical repair can be done from either a thoracic or an abdominal approach The latter was used in 57% of the cases and has the advantage that it may lead to the recognition and correction of intra abdominal disease Relief of symptoms was accomplished in most patients The observed recurrence rate of 10% or more was such as to discourage attempts to repair small, asymptomatic esophageal hiatal hernias*

Endeavors to repair hernias through the esophageal hiatus extend far back into surgical history Certain landmarks are recognizable along the way, noteworthy being the concepts developed and practiced by Harrington [1] and the technique introduced by Allison [2] In spite of accumulating experience, confusion still exists concerning indications for operation, operative techniques, and results of surgical treatment

Detailed analysis of indications for operation is beyond the scope of this study, which was undertaken to evaluate objectively an experience with esophageal hiatal hernias on two surgical services at the Mayo Clinic from 1952 through 1955 Particular attention was paid to operative techniques and results of surgical intervention

Present Study

A total of 113 patients were operated on for esophageal hiatal hernias on these two services in the four-year period This series included 54 men and 59 women Their ages ranged from 25 to 79 years, with an average age of 51 years

Symptoms and Signs —Before operation, 78% of the patients had experienced symptoms attributable to the hiatal hernia The commonest complaint was substernal burning distress, while dysphagia or regurgitation was noted by about a third of the patients Gastrointestinal bleeding had been present in 19% of the patients

Roentgenoscopic and roentgenographic studies were done on all patients, the hernia was demonstrated by this method in all but one Preoperative esophagoscopic studies were done on 80 of the 113 patients, esophagitis with or without ulceration was noted in 44% of the patients thus examined

Type of Esophageal Hiatal Hernia —A useful classification categorizes diaphragmatic hernias according to four anatomic locations (see table) This study is concerned only with hernias through the esophageal hiatus Since esophageal hiatal hernias with significant esophageal shortening have not been treated by simple repair at the clinic, such cases are not included in this series A total of 97 hernias were of the sliding type, and 16 (14%) were of the paraesophageal type

Classification of Diaphragmatic Hernias

- Hernias through esophageal hiatus
    - Esophagogastric junction in normal position (paraesophageal type)
    - Elevation of esophagogastric junction (sliding type)
        - Esophagus nearly normal in length
        - Esophagus short
- Hernias through foramen of Morgagni
- Hernias through foramen of Bochdalek (hiatus pleuroperitonealis)
- Hernias through dome of diaphragm

Anatomic Considerations

The esophageal hiatus in most instances lies within the right (muscular) crus of the diaphragm,[3] the fibers of which split to encircle the esophagus, forming a sling that is attached by tendinous bands to the lumbar vertebrae The actual attachment of the esophagus to the diaphragm is ligamentous The lining of the abdominal parietes, the transversalis fascia, is reflected over the undersurface of the diaphragm as the diaphragmatic fascia and ascends through the muscular hiatus to insert about the entire circumference of the thoracic portion of the esophagus 2 to 3 cm above the esophagogastric junction The fascia passing from the diaphragm to the esophagus is known as the phrenoesophageal (diaphragmaticoesophageal) membrane

The peritoneum is intimately attached to the body of the stomach, except at its curvatures, but is separated from the esophagogastric junction by fatty tissue and becomes loose anteriorly During abdominal exploration, the surgeon may invaginate the lax peritoneum through the hiatus, but the intact phrenoesophageal ligament limits this maneuver in the normal person

The basic structural defects are somewhat different in sliding and in paraesophageal varieties of hernia At least three defects are present in the sliding variety, namely (1) a redundant peritoneal sac that ascends through the hiatus on the anterolateral aspect of the upper part of the stomach and the lower part of the esophagus, (2) a phrenoesophageal ligament that is stretched chiefly in its anterolateral aspect, and (3) distortion of the muscular collar of the hiatus, mostly

---

From the Section of Surgery (Drs Kirklin and Clagett) and the Section of Medicine (Dr Andersen), the Mayo Clinic and Mayo Foundation Dr Myre is a Fellow in Surgery of the Mayo Foundation The Mayo Foundation is a part of the Graduate School of the University of Minnesota

Read before the Section on Surgery, General and Abdominal, at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956 in the posterior and inferior aspects These defects allow the esophagogastric junction to ascend and cause the esophagus to be displaced posteriorly, destroying the anterior inclination of the lower part of the esophagus

The defects in the paraesophageal variety are at least two in number, namely (1) a redundant peritoneal sac and (2) distortion of the muscular collar as just described *The phrenoesophageal membrane is* functionally competent and the esophagogastric junction is at its normal position

Surgical Repair

An abdominal approach was used in 57% of the cases in this series, whereas the repair in 36% was accomplished through a transthoracic approach In a few cases, under special circumstances, a left thoracoabdominal incision was used

Two important facts must be emphasized as being related to the surgical approach for repair of esophageal hiatal hernia In the first place, the identical repair can be effected working either above or below the diaphragm Secondly, certain patients with esophageal hiatal hernias have associated pathological changes in the abdomen for which operation is likewise advisable Other abdominal surgical procedures were deemed necessary at the time of repair of the hiatal hernia in 40 cases, or 35% of the entire group A cholecystectomy was performed in 27 cases, a partial gastrectomy in 10 cases, an excision of gastric ulcer and gastroenterostomy in one case, a total gastrectomy in one case, and a pyloromyotomy in one case

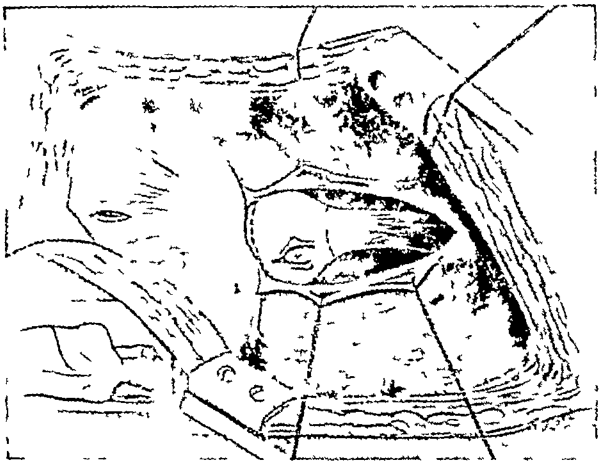

Fig 1 —Esophageal hiatal hernia as seen through thoracotomy incision Note that phrenoesophageal ligament covers herniated portion of stomach Segment between dotted lines represents amount of phrenoesophageal ligament that may be excised

A further consideration is that symptoms such as substernal pain or massive gastrointestinal hemorrhage may or may not originate in the demonstrated esophageal hiatal hernia in a given patient It is reassuring, in such instances, to be in a position to manage an unexpectedly encountered duodenal ulcer, for example

A reasonable plan, employed in this series, is to select the method of approach on the basis of conditions pertaining to the individual patient A transthoracic approach is indicated for patients in whom exposure of the esophageal hiatus may be unusuall difficult by the abdominal approach, such as obes persons or men in whom the thorax is deep Also, th transthoracic approach appears preferable when concern exists about the length of the esophagus, as in patient with secondary ulcerative esophagitis Operation is done, preferably by the abdominal route, o patients with known coexisting upper abdomina disease for which operation appears indicated, th obviates a second operation Patients whose symptom might be the result of unsuspected abdominal lesion primarily those who have bleeding as the presentin complaint, are best operated on through the abdomen

Surgical Technique—The repair of esophagea hiatal hernia is directed toward correction of the defects already enumerated This might entail (1) incision of the attenuated portion of the phrenoesophageal ligament and suture of the esophageal portion t the cut edge of the diaphragmatic fascia and (2 reapproximation of the two limbs of the right cru behind the esophagus Harrington [1] pointed out tha these are sliding hernias, inasmuch as a part of th sac consists of the wall of a viscus As in the repa of sliding hernias in other locations, management o the peritoneal sac does not play a significant role i the repair

Repair by Thoracic Route In *repair by the thoracic route*, a posterolateral incision is made and th left hemithorax is entered through the eighth interspace The mediastinal pleura is incised over the lowe portion of the esophagus, this incision being carrie down to the diaphragm The pleura is reflected off th superior aspect of the left limb of the right crus of th diaphragm so that this is clearly seen The right liml of the right crus is seen passing forward to the centra tendon of the diaphragm it lies deep to the herniate portion of the stomach in this exposure The bar lower part of the esophagus is clearly seen and i mobilized, along with both vagus nerves A tape i passed around it The herniated portion of stomac and peritoneum is seen to be invested by attenuate phrenoesophageal ligament (fig 1), which is attache to the lower part of the esophagus

A short (2-cm) incision is made in the diaphragm this is not located in the thin dome but is placed in th *peripheral muscular portion The surgeon passes* tw fingers through this incision and up into the peritonea sac With these fingers as a guide, the phrenoesophageal ligament is cleanly incised, with a fringe lef attached to the muscular hiatus for later placemen of sutures The peritoneal sac is then opened widel and its attachments liberated sufficiently so that th hernia is easily reduced The tape previously place around the lower portion of the esophagus is passe into the abdomen through the hiatus and then retrieved through the stab wound in the periphery o the diaphragm Traction on this tape maintains reduction of the hernia and keeps the esophagogastri junction well below the diaphragm during repair

Interrupted 00 silk sutures are placed to approximate the two limbs of the right crus of the diaphragn behind the esophagus (fig 2) Two to four stitche usually suffice to narrow the hiatus until the index finger can just be inserted into it beside the esophagus. In some cases in this series, the remnant of phrenoesophageal membrane on the esophagus was sutured with interrupted 000 silk sutures to the fringe that was left continuing through the hiatus. This portion of the repair can be accomplished accurately at times, but at other times it leaves something to be desired. The tape is removed and the small incision in the periphery of the diaphragm is closed with 000 silk sutures. The mediastinal pleura is loosely closed over the operative site. The thoracic wall is closed in layers. A catheter is left for temporary closed intercostal drainage.

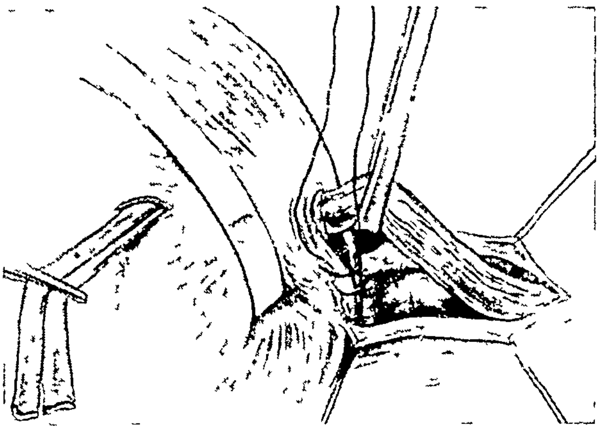

Fig 2.—Approximation of two limbs of right crus behind esophagus. (Hernia has been reduced.) Stitches have been placed for reconstruction of phrenoesophageal ligament.

Repair by Abdominal Route. In repair by the abdominal route, an upper midline abdominal incision often allows good exposure for the repair. A slightly arched transverse or straight transverse upper abdominal incision is preferable at times in patients with wide costal arches (fig 3).

The esophageal hiatus is exposed by incising the triangular ligament so that the left lobe of the liver can be mobilized and retracted to the right. Although some techniques require mobilization of the spleen, this is an unnecessary maneuver. The anterior wall of the stomach is grasped, and traction applied to it reduces the hernia. The loose peritoneum over the esophagogastric junction is incised, and the redundant peritoneum of the sac is pulled down from the mediastinum and excised. From the abdominal side, the phrenoesophageal membrane may not be seen as clearly at this stage as it is during operation through the thoracic approach. A tape is placed around the lower part of the esophagus, and traction on it maintains the reduction (fig 3). The two limbs of the right crus of the diaphragm then can be seen behind the esophagus as this structure is retracted forward by the surgeon's hand.

Repair is accomplished by suturing together the two limbs of the right crus behind the esophagus, exactly as described for repair by the transthoracic route (fig 3). Portions of the phrenoesophageal ligament still attached to the esophagus have then been sutured to the diaphragmatic fascia and to the peritoneum around the hiatus in some cases.

Results

As already indicated, 113 patients were operated on. One postoperative death occurred. This was in a patient in whom repair was accomplished by the transthoracic route. Death took place on the 33rd postoperative day as the result of pseudomembranous ileocolitis. The average stay in the hospital was 10.6 days in those operated on with the transthoracic approach and 10.2 days in those operated on with the abdominal approach. The incidence of nonfatal complications, such as thrombophlebitis, was not noticeably different in the two groups.

Relief of symptoms has been accomplished in most patients. Follow-up information is available on 68 of the 88 patients who had symptoms referable to the hiatal hernia. In 62 cases (91.2%) there had been complete relief, in 3 cases (4.4%) partial relief, and in 3 cases (4.4%) no relief of symptoms. The data indicate that more than 90% of that group had symptomatic relief after operation.

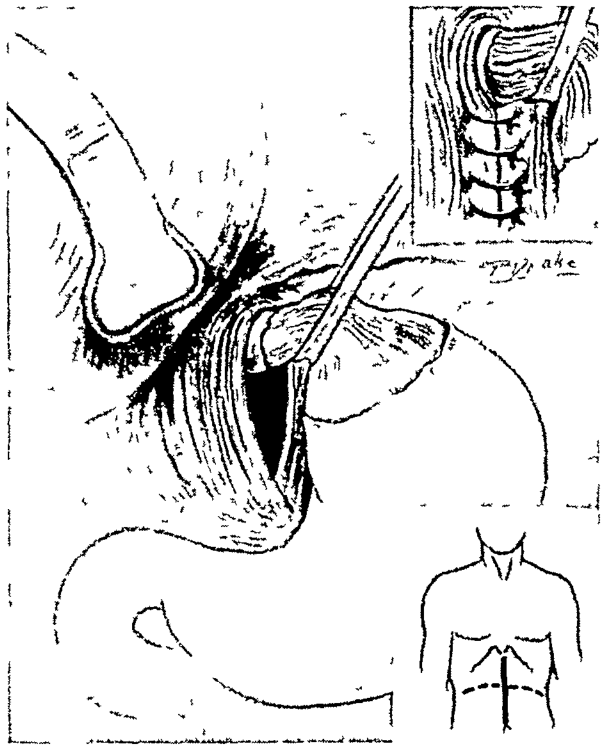

Fig 3.—Exposure of esophageal hiatal hernia through abdominal approach. Note clear exposure of two limbs of right crus behind esophagus. Lower insert shows usual incisions, midline or transverse. Upper insert shows repair by the Allison technique. Note that anatomic repair is similar to that obtained when repair is made from above diaphragm.

Unfortunately, of the 113 patients, only 48 had postoperative roentgenologic examination of the esophagus and stomach, and in some instances this was relatively soon after operation. Evidence of recurrence was noted in 5 (10%) of these 48 patients. These five included the three patients who did not experience any symptomatic relief from the operative procedure In view of the relatively short period between operation and examination in some cases, it is clear that this is a minimal figure for recurrence and that longer follow-up may show it to be somewhat higher

Comment

Two points appear worthy of emphasis First, satisfactory repair of esophageal hiatal hernia by the Allison [2] technique unquestionably can be accomplished by either the abdominal or thoracic approach Therefore, other factors, as already discussed, should determine the approach to be employed in a given patient

Secondly, evidence is clear that recurrence may take place after repair of an esophageal hiatal hernia The incidence of such recurrence reported in the literature varies from 3 to 50% [4] As already emphasized, the recurrence rate of 10% in our series is certainly minimal and may increase as these patients are followed up for longer periods Such a recurrence rate must stimulate continuing study of the technical problems of repair Knowledge of this recurrence rate also must temper the surgeon's enthusiasm for the repair of small asymptomatic esophageal hiatal hernias

Summary

A study has been made of 113 patients on whom operations were done for esophageal hiatal hernias in a four-year period at the Mayo Clinic Preoperative symptoms attributable to the hernias had been present in 78% of these patients The lesion was demonstrable by roentgenologic methods in all but one of the 113 patients

An abdominal approach was used for the surgical repair in 57% of the patients, whereas a transthoracic incision was utilized in 36% A left thoracoabdominal approach was used in a few patients An abdominal approach is advisable if any possibility exists of associated abdominal disease that may require surgical correction

Postoperative symptomatic relief was experienced by more than 90% of those who had preoperative symptoms One death occurred after operation, this resulted from pseudomembranous ileocolitis The recurrence rate relatively early in the postoperative course was 10%, indicating that this rate might be greater after longer follow-up

PRIMARY MILIARY TUBERCULOSIS OF THE LIVER

R Barratt Terry, M D
and
Rolf M Gunnar, M D , Chicago

• *Primary miliary tuberculosis of the liver was found in 12 cases under conditions showing that it is not rare but is easily overlooked as a possible cause of obscure illness The symptoms found in all these case histories included fever, lassitude, weakness, anorexia, weight loss, chills, and drenching sweats Reaction to the Mantoux test was positive in all No cases of jaundice were seen Hepatomegaly, splenomegaly, ascites, alcoholism, and exposure to tuberculosis are clues to the diagnosis Needle biopsy of the liver is valuable but need not be done immediately in very weak patients, since recognizable tubercles remain in the liver for weeks after successful therapy has started Isoniazid and amino salicylic acid are now given to every patient, with streptomycin and steroids if necessary The response in the cases here described was remarkably good, and sometimes dramatic All of the eight patients whose treatment was considered adequate recovered without sequelae*

Miliary tuberculosis of the liver tends to be disregarded as a cause of obscure illness, pyrexia, or hepatomegaly This disregard presumably stems from the past, when such a diagnosis was an empty clinical triumph The physician could establish it only by laparotomy, a hazardous procedure in patients with such conditions, and, having made the diagnosis, he remained therapeutically impotent Nevertheless the concept of tuberculosis chiefly confined to the liver was recognized and, after the first description by Bristowe in 1858,[1] there were scattered contributions to the subject [2] In recent years there has been a radical change in the situation The demonstration of tubercles in the liver has become a relatively safe and simple matter with the advent of modern liver biopsy techniques,[3] and treatment of this condition with the new antituberculosis agents is remarkably efficacious

---

From the Department of Medical Education and the Hektoen Institute for Medical Research of the Cook County Hospital, and the departments of medicine of Northwestern University and the University of Illinois

Experience indicates, however, that the old attitude has not as yet been changed by the new situation One reason for this may well be that isolated hepatic tuberculosis was, and still is, considered to be rare, another is simply that attitudes are slow to change The purpose of this paper is, therefore, to report 12 cases of miliary tuberculosis chiefly confined to the liver that were encountered by us over a period of four years and to outline the clinical picture and the management of such cases

Definition and Nomenclature

The term "primary miliary tuberculosis of the liver' is used in this paper to indicate a condition in which there is hematogenous dissemination of tuberculosis to the liver, with minimal involvement of other organs In particular, no cases have been included in which there was radiologic evidence of pulmonary tuberculosis, miliary or other, except late in the disease when the infection often becomes generally disseminated Specifically excluded by this definition is the incidental involvement of the liver so common in pulmonary tuberculosis and in generalized miliary tuberculosis

Nomenclature is unsatisfactory at present, as indicated by the many different names that have been used in the past 'Primary tuberculosis of the liver" [2a] is inaccurate, because the condition is invariably secondary to tuberculosis elsewhere, usually in the regional nodes, and, for the present purpose, it is too inclusive, for it also covers massive tuberculous abscesses and tuberculomas, which form a separate group "Acute pylephlebogenous tuberculosis of the liver" [2b] is applicable to acute cases, which form only a part of the present series, and it ignores the possibility of the hepatic arterial route of infection "Conglomerate tuberculosis of the liver,' 'tuberculous cholangitis,' 'tubular tuberculosis of the liver, and "disseminated caseating tuberculosis of the liver' are pathological diagnoses, descriptive of the autopsy findings but not helpful to the clinician "Atypical tuberculosis of the liver" [4] suggests that there is a typical form, which is doubtful The cases described under the term "atypical abdominal tuberculosis' [5] have many of the features of the series under discussion, but there seems to be little reason to incriminate the whole abdomen or to suppose that there is a typical form of abdominal tuberculosis Tuberculous hepatitis' [6] is a neat term but has little other merit, and certainly there is scanty evidence of hepatitis 'Hepatic tuberculosis" is much too inclusive, as is 'hepatolienal tuberculosis' 'Tuberculous portal pyaemia" [7] is an attractive term, but it indicates abscess formation and infection via the portal vein, neither of which is correct in any given case 'Miliary tuberculosis of the liver' and 'acute miliary tuberculosis of the liver" both seem to require further qualification Thus, 'primary miliary tuberculosis of the liver is considered to describe the condition under discussion more accurately and with fewer disadvantages than other terms

Report of Cases

The 12 examples of primary miliary tuberculosis of the liver described here were encountered between May, 1951, and August, 1955 The patient in case 1 was seen at the Seamen's Hospital, London, the patient in case 2 at a private hospital in Chicago, and the rest of the patients at Cook County Hospital, Chicago The cases are presented according to the manner of diagnosis and management

Diagnosis Unsuspected During Life and Revealed at Autopsy

Case 1 —A 62-year-old white man entered the hospital on May 1, 1951 For three months he had had vague but increasing malaise, anorexia weight loss, and occasional diarrhea For three weeks there had been severe night sweats, and for 10 days there had been remittent fever, with temperatures reaching 104 F (40 C) with rigors Exposure to tuberculosis or to alcohol was not discussed When he entered the hospital the patient was wasted and acutely ill with a temperature of 102 F (38 9 C) and pulse of 120 per minute There were no signs in the chest The liver was enlarged to 7 5 cm below the costal margin with a firm nodular surface The spleen was enlarged to 2 0 cm below the costal margin Urinalysis showed a trace of albumin X-ray of the chest showed entirely normal lung fields The icteric index was 20 units The hemogram showed anemia and leukopenia (see table) Liver biopsy to establish the diagnosis of lymphoma or carcinomatosis was considered but rejected because the patient was so ill The possibility of tuberculosis was never considered The patient s condition steadily deteriorated, and he died six weeks after admission Autopsy revealed numerous large tubercles, measuring up to 20 mm in diameter, in the liver, and there were similar small tubercles in the spleen The retroperitoneal and mediastinal lymph nodes were enlarged and caseous One large celiac node was calcified The lungs were not involved by the miliary process Microscopic examination revealed tubercle bacilli in moderate numbers in the liver and nodes, there was much necrosis in the hepatic lesions with occasional giant cells but with little cellular reaction

Primary miliary tuberculosis of the liver, which spread ultimately to the spleen and regional nodes caused an illness of five months' duration that was fatal Nodular hepatomegaly was an outstanding clinical feature

CASE 2 —A 35 year-old white woman entered the hospital on Dec 21 1952 She had been drinking excessively for at least five years For three months she had been too weak to work For several weeks she had suffered from fever and shaking chills and epigastric pain and had noticed dark urine and pale stools Her father brother, and husband had all died of tuberculosis She was icteric and moderately obese Her temperature was 104 F (40 C) pulse 132 per minute, and respirations were 24 per minute The liver was palpable 13 cm below the costal margin and it was tender The spleen was not enlarged The urine contained moderate amounts of bile and urobilinogen The reaction to the Mantoux test was positive with 1 10,000 old tuberculin Repeated chest x-rays revealed entirely normal lung fields The liver profile showed icteric index 64 units alkaline phosphatase level 9 Bodansky units total serum protein level 8 gm per 100 cc cephalin flocculation, no precipitate thymol turbidity 6 7 units gamma globulin level, 1 70 gm per 100 cc and total serum cholesterol level 438 mg per 100 cc Hepatic tuberculosis was not among the many diagnoses considered After she spent four weeks with remittent fever with temperatures that frequently reached 104 5 F (40 3 C) an impatient intern prescribed injections of a penicillin-streptomycin compound after which the patient became afebrile and improved sufficiently to be discharged The significance of this response to therapy was overlooked, and she left the hospital on Feb 2 1953 without tuberculosis being considered On March 21 1953, she was readmitted in coma, and no further history was available Her temperature was 105 F (40 5 C) Her liver was now enlarged to only 5 cm below the costal margin A partial liver profile was negative (see table) She rallied briefly, but developed hemiplegia on the right and died 11 days after admission Autopsy revealed innumerable tubercles in the liver which was not cirrhotic There were also miliary tubercles in the lungs spleen and kidneys and three small tuberculomas in the brain

Primary miliary tuberculosis of the liver in a chronic alcoholic caused an illness of six months' duration that was fatal The condition was masked by inadequate and unintentional antituberculosis therapy There was terminal involvement of the lungs and meninges

Primary Miliary Tuberculosis of Liver Diagnosed During Life, but Too Late for Effective Therapy

CASE 3 —A 56-year-old Negro man entered the hospital on June 3 1952 with a history of six months of vague ill health lassitude poor appetite and loss of weight For one month he had experienced severe backaches pain in the upper part of the abdomen on the right epigastric discomfort fever and chills His family history was negative for tuberculosis He had consumed large amounts of alcohol for many years He was thin and acutely ill, with temperature 102 F (38 9 C) pulse 108 per minute, and respirations 20 per minute The liver was enlarged to 12 cm below the costal margin and to 12 cm below the xiphosternum The spleen was not palpable He had remittent fever with temperatures up to 102 F (38 9 C) each evening X-rays of the chest showed normal lung fields He felt much better after several days in bed and discharged himself against medical advice Repeated x-rays of the chest just before this discharge were again entirely normal He slowly grew weaker and reentered the hospital on Sept 22 1952 He was cachectic and obviously very ill His temperature was 102 F (38 9 C) and pulse 120 per minute Fine moist rales were heard throughout both lung fields The liver was enlarged to 15 0 cm below the right costal margin and to 17 5 cm below the xiphosternum It was tender and the surface was nodular X-ray of the chest revealed diffuse nodular opacities suggestive of miliary tuberculosis Three sputum specimens were negative for tubercle bacilli The liver profile was abnormal (see table) Hepatic tuberculosis was among the diagnoses considered but before any decision was made regarding therapy, the patient died on Oct 20, 1952 Autopsy revealed a huge liver with many large and small pale nodules These were initially considered to be lymphomatous, but microscopy revealed that they were tuberculous There were also miliary lesions of the lungs and spleen and the mesenteric para-aortic, and tracheobronchial lymph nodes

Primary miliary tuberculosis of the liver in a chronic alcoholic caused an illness of 10 months duration that was fatal Terminally the liver became grossly nodular and there was dissemination to the lungs

CASE 4 —A 47-year-old Negro man entered the hospital on June 29 1955, in a state of confusion with a vague history of at least six months of weakness More recently he had noticed a lump in his neck He had consumed 1 pt of whiskey a day for many years He was thin lethargic and irritable His temperature was 101 F (38 3 C), pulse 100 per minute, and respirations were 20 per minute The pupil of the right eye was smaller than that of the left Moderate neck rigidity was present A firm mobile, nontender lymph node, 3 cm in diameter, was felt behind the clavicular head of the left sternocleidomastoid muscle The abdomen was somewhat distended, in marked contrast to the general wasted appearance The liver and spleen were not felt X-ray of the chest was negative The liver profile was abnormal (see table) and was considered to indicate a diagnosis of Laennec s cirrhosis especially in view of the alcoholic history The cerebrospinal fluid, however, contained protein, 140 mg per 100 cc , glucose, 80 mg per 100 cc , and chlorides, 104 mEq per liter In view of this, the enlarged cervical node, and the anisocoria a diagnosis of disseminated tuberculosis was made Streptomycin, isoniazid (INAH), and aminosalicylic acid (PAS) were administered After slight improvement, the patient relapsed and died on the fourth day of treatment The autopsy revealed that the liver weighed 2,000 gm and contained innumerable tubercles varying from 1 0 mm to 1 5 cm in diameter Many tubercles were so solid and fleshy that the differentiation from lymphoma had to await histological examination It also showed tuberculosis of the portal, mesenteric para-aortic tracheobronchial and left supraclavicular lymph nodes and early meningeal tuberculosis There was no evidence of pulmonary tuberculosis

Primary miliary tuberculosis of the liver in a chronic alcoholic caused an illness of six months' duration that was fatal There was terminal spread to the meninges and regional nodes, but not to the lungs

Primary Miliary Tuberculosis of Liver Correctly Diagnosed and Needle Biopsy Performed After Therapy

CASE 5 —A 33-year-old Negro man entered the hospital on Aug 16, 1955 For four weeks he had been listless and his abdomen gradually had become swollen without any other symptoms A rigor occurred on the day of admission He had been drinking heavily on week ends for 10 years When he had been 2 years old a brother and a sister had died of pulmonary tuberculosis On admission to the hospital he showed no obvious loss of weight and looked remarkably well His temperature was 102 6 F (39 2 C) and pulse 100 per minute No enlarged lymph nodes were felt The abdomen was markedly distended, with shifting dulness in the bulging flanks X-ray of the chest showed normal lung fields X ray of the abdomen revealed several calcified shadows in the epigastric region which were interpreted as calcified lymph nodes The reaction to the Mantoux test was positive with 1 10 000 old tuberculin The liver profile was abnormal (see table) Paracentesis obtained 4 700 cc of straw-colored ascitic fluid with a protein content of 5 0 gm per 100 cc , a protein content of 6 2 gm per 100 cc was obtained in a second paracentesis After paracentesis, the liver was found to be enlarged to 7 5 cm and the spleen to 2 0 cm below the costal margin A clinical diagnosis of hepatic tuberculosis was made and isoniazid aminosalicylic acid and streptomycin were administered He became afebrile in five days Five weeks later the ascites had cleared and a liver biopsy was performed It revealed a granulomatous hepatitis compatible with tuberculosis Two months after therapy was begun, the liver and spleen had become impalpable Recovery was complete and uneventful

Primary miliary tuberculosis of the liver in a chronic alcoholic led to fever and ascites Needle biopsy was contraindicated initially Antituberculosis therapy was therefore given and diagnostic liver biopsy performed when sufficient improvement had occurred The clinical diagnosis was confirmed by the liver biopsy 37 days after the onset of effective therapy

Case 6 —A 51-year-old Negro man entered the hospital on March 28, 1953 For one week he had experienced drenching sweats and feverishness every evening and also frontal headache cramping upper abdominal pain, and loose stools Family history was negative for tuberculosis He had consumed excessive amounts of alcohol for many years When he entered the hospital, he was emaciated and extremely ill his temperature was 103 F (39 4 C), and his pulse was 88 per minute The abdomen was distended there was tympanites without evidence of ascites The liver was enlarged to 7 cm below the right costal margin The spleen was not enlarged X-ray of the chest showed entirely normal lung fields X-ray of the abdomen revealed a calcified density just to the right of the first lumbar vertebra that was interpreted as a calcified abdominal lymph node Reaction to the Mantoux test was positive with 1 1 000 old tuberculin The liver profile was not remarkable (see table) On April 24 a clinical diagnosis of hepatic tuberculosis was made The patient was judged to be too ill for liver biopsy and treatment was commenced with streptomycin and isoniazid Within three days there was a dramatic improvement and he was afebrile within two weeks A liver biopsy performed after 25 days of treatment revealed miliary granulomas compatible with tuberculosis Recovery was uneventful and complete When the patient was admitted his white blood cell count was 5 000 per cubic millimeter, but this steadily decreased until it reached 800 per cubic millimeter By this time specific therapy had started and the count rapidly rose to reach 5 200 per cubic millimeter after six days of therapy This leukopenia was considered to result from involvement of the bone marrow

Primary miliary tuberculosis of the liver caused pyrexia and hepatomegaly It eventually spread to the bone marrow The diagnosis was confirmed by liver biopsy after 25 days of specific therapy

Case 7 —A 27-year-old Negro woman entered the hospital on May 29, 1953 For two weeks she had had malaise anorexia recurrent chills and a slight productive cough Three days before admission she had noticed submammary pain on the left that was worse on coughing or with deep breathing She then began to feel very much more ill the chills became more severe and she started to vomit There was no known exposure to tuberculosis She had overindulged in alcohol for many years and for at least 12 months had consumed not less than 1 pt of whiskey a day She was well developed well nourished, and appeared anxious and ill Her temperature was 103 F (39 4 C) and pulse 132 per minute There were no enlarged lymph nodes There was no pleural friction rub The liver was enlarged to 3 cm below the costal margin The spleen was not enlarged Urinalysis revealed 3+ urobilinogen The hemogram was not remarkable The liver profile showed some decrease of albumin and increase of globulin but was otherwise normal (see table) The reaction to the Mantoux test was positive with 1 1 000 old tuberculin Six x-rays of the chest, taken between May 29 and Aug 10 showed normal lung fields and no pleural effusion She was considered to have hepatic tuberculosis, but, as her condition was so poor, liver biopsy was postponed Streptomycin, 1 gm daily, and aminosalicylic acid 12 gm daily were administered Little response was obtained, on June 18 a node was found in the right axilla and the spleen was palpable 3 5 cm below the costal margin On June 24, therapy with isoniazid (but only 100 mg twice a day) was started, there was a rapid improvement and she became afebrile after two weeks A liver biopsy was performed four weeks after therapy had been started and revealed numerous active, though noncaseating tubercles Recovery was complete and uneventful

Primary miliary tuberculosis of the liver in a chronic alcoholic was confirmed by liver biopsy after four weeks of treatment Streptomycin alone was given initially, but was ineffective and recovery occurred only after the addition of isoniazid

Primary Miliary Tuberculosis of Liver Diagnosed Clinically and Confirmed by Needle Biopsy Before Therapy

Case 8 —A 52-year-old white man entered the hospital on Aug 21 1953 For one week he had had chills fever mental confusion and myalgia which had started suddenly He appeared remarkably well, except during and shortly after his frequent bouts of fever He had an intermittent fever, with temperatures up to 102 5 F (39 2 C) sometimes twice daily His pulse rate was 40 per minute (complete heart block following coronary thrombosis seven years previously) There were no localizing physical signs, but after one week a cervical lymph node enlarged and the liver and spleen became palpable X-ray of the chest was negative save for a small area of pneumonitis at the base of the left lung The hemogram showed no anemia The liver profile was abnormal (see table) Examination of the sternal marrow showed a toxic reaction Biopsy of the cervical lymph node revealed a small noncaseating, nonspecific granuloma The problem of the cause of this obscure fever was complicated by a history of amebic colitis and by the fact that a business partner of the patient had recently had brucellosis A five day course of streptomycin therapy produced no effect on the fever or on his condition subjectively or objectively, and was abandoned on the presumption that the illness was not tuberculous in origin Needle biopsy of the liver was performed on the 35th day of the patient's illness and revealed numerous caseating granulomas indicative of tuberculosis Treatment with isoniazid, aminosalicylic acid and streptomycin resulted in a dramatic improvement followed by complete recovery, with no relapse 30 months later

Primary miliary tuberculosis of the liver caused an obscure pyrexial illness Treatment with streptomycin alone for a trial period of five days was ineffective Liver biopsy, however, revealed the true diagnosis There was a rapid response to isoniazid

Case 9 —A 32-year old Negro woman entered the hospital on Oct 30 1953 In 1950, an enlarged lymph node had appeared on the left side of her neck a biopsy revealed tuberculosis The node gradually disappeared without treatment In May, 1952 a left cervical node enlarged biopsy was performed tuberculosis was demonstrated and it again disappeared without treatment In February 1953 a tender node appeared in the left axilla it did not disappear Following the delivery of her ninth child in September 1953, the patient began to have aching pains in the hips and calves on walking and gradually became more listless When she entered the hospital, she appeared moderately ill but with no obvious loss of weight Temperature was 101 F (38 2 C) and pulse 100 per minute Several enlarged nodes were present in the left axilla but not elsewhere The liver was just palpable and the spleen was enlarged to 2 cm below the costal margin X-rays of the chest on four occasions showed normal lung fields The liver profile was abnormal and she was anemic (see table) The reaction to the Mantoux test was positive with 1 10,000 old tuberculin and produced central necrosis Biopsy of the left axillary node revealed caseous tuberculosis Liver biopsy revealed numerous tubercles Treatment with isoniazid, aminosalicylic acid and streptomycin resulted in a rapid and complete recovery

Primary miliary tuberculosis of the liver was apparently precipitated by childbirth in this case There was also tuberculosis of an axillary lymph node

CASE 10 —A 22-year old Negro woman entered the hospital on July 22 1954, with a year's history of lumps on her shins that later ulcerated and persisted For six months she had had a poor appetite and she had lost 40 lb (18 1 kg) in weight One month before admission she had had her chest x-rayed at the Municipal Tuberculosis Sanitarium, with negative results An uncle and a brother had died of tuberculosis She was moderately emaciated, with a temperature of 102 F (38 9 C) and pulse 140 per minute The abdomen was distended The liver was enlarged to 4 cm below the costal margin, and the spleen to 3 cm Small scattered ulcers were present on her shins X-ray of the chest revealed a small pleural effusion on the left The hemogram showed marked anemia Her liver profile was abnormal (see table) Liver biopsy revealed numerous tubercles By the time that treatment was started with streptomycin 1 gm twice a day her temperature had reached 105 F (40 5 C) daily On the fourth day of therapy, she was afebrile Isoniazid and aminosalicylic acid were added to the regimen 10 days later and recovery was both rapid and uneventful

Primary miliary tuberculosis of the liver caused a severe febrile illness in a young woman who had a strong family history of tuberculosis and who developed erythema induratum at the onset Streptomycin alone produced a remarkable improvement within four days

CASE 11 —A 17 year old Negro man entered the hospital on May 22 1954 For seven days he had experienced a dull aching periumbilical pain that had started rather suddenly and then persisted His abdomen had gradually swelled over the same period He denied exposure to either tuberculosis or alcohol He was thin and moderately ill with a temperature of 101 5 F (38 6 C) and pulse 100 per minute The abdomen was distended, and there was evidence of ascites X-ray of the chest showed normal lung fields The reaction to the Mantoux test was positive with 1 100 old tuberculin The hemogram showed some leukopenia The liver profile was normal (see table) Paracentesis obtained 4 500 cc of straw-colored fluid with a specific gravity of 1,018, the protein content was not estimated For six weeks the temperature ranged to 102 F (38 9 C) daily and his condition steadily deteriorated Liver biopsy was then performed and revealed numerous caseating tubercles He was then placed on streptomycin therapy and rapidly improved He was transferred to the tuberculosis sanatorium

Primary miliary tuberculosis of the liver was complicated by ascites The diagnosis was eventually established by liver biopsy, and streptomycin alone resulted in rapid improvement

Primary Miliary Tuberculosis of Liver Suspected Clinically and Confirmed by Favorable Response to Therapy

CASE 12 —A 29 year-old Negro man entered the hospital on Feb 5, 1954 For two weeks he had suffered from recurrent attacks of severe griping epigastric pain These had been gradually easing but for 10 days he had noticed that his abdomen was swelling He had also had fever, with temperatures up to 102 F (38 9 C), night sweats anorexia, loss of weight and some diarrhea There was no history of exposure to tuberculosis or alcohol He was thin, pale, and appeared chronically ill His temperature was 98 F (36 7 C) and pulse 96 per minute The abdomen was moderately distended with central tympany and demonstrable ascites The liver was enlarged to 5 cm below the costal margin The spleen was not palpable X-ray of the chest showed normal lung fields The hemogram showed slight anemia, and the liver profile was normal (see table) A liver biopsy revealed a nonspecific granulomatous hepatitis, with numerous small follicles Treatment with isoniazid and streptomycin resulted in a rapid uneventful recovery, with disappearance of the ascites and the hepatomegaly This therapeutic result was accepted as proof of the tuberculous nature of the hepatic follicles

Primary miliary tuberculosis of the liver was suggested by the demonstration of nonspecific hepatic granulomas and confirmed by the rapid response to isoniazid and streptomycin

Clinical Aspects

The symptoms found in all these cases of primary miliary tuberculosis of the liver included histories of nonspecific, toxic, febrile lassitude, weakness, anorexia, weight loss, fever, chills or rigors, and drenching sweats Respiratory symptoms were conspicuous by their absence Jaundice was not an appreciable feature of the present series, although it undoubtedly does occur in hepatic tuberculosis, the initial jaundice of the patient in case 2 cleared without therapy and was considered to be primarily a toxic hepatitis affecting the fatty liver of an alcoholic Abdominal symptoms were common, ill-defined pain or discomfort in the epigastrium predominated In three patients, abdominal swelling was the presenting complaint Diarrhea was present in two cases, but was not troublesome in either

A family history of tuberculosis was only detected in three patients, but many of the other patients were vague about their relatives, and their negative histories are of dubious value More interesting, and possibly more significant, was the excessive consumption of alcohol admitted by six patients The prevalence of this factor was not initially recognized, and relevant inquiry was not always pursued

On physical examination, most of the patients were obviously seriously ill, and all but two had lost weight The patient in case 3, however, had been little incapacitated during the first five months of his illness, the patient in case 5 looked remarkably well with no obvious loss of weight, the patient in case 8 looked and felt comparatively normal, except when experiencing a rigor, and the patient in case 9 had lost no weight and seemed only moderately ill In the Negro patients, a common feature was the loss of the normal sheen of the skin, in many instances the skin looked as if it had been powdered, especially on the shins and forearms In striking contrast to the general thinness, the abdomen often appeared to be well nourished or 'full', closer examination, however, indicated that this fulness came from within, and that it was due, apparently, to hepatomegaly and probably some degree of ascites The liver was palpated in all but four instances, and was markedly enlarged in two The spleen was felt in seven patients, and was large in none In several, there was a hint of ascites and some gaseous distention, and in three there was frank ascites An enlarged lymph node was palpable in three patients

The reaction to the Mantoux test was positive in all cases in which it was done Roentgenography of the chest was negative in every case, at any rate until the later stages of the disorder X-ray studies of the abdomen showed what were presumed to be calcified lymph nodes in the upper abdomen in three cases

Hemograms were nonspecific, in general, there was a endency to anemia and leukopenia (see table) The able also shows that the liver profile often indicated changes in serum protein values No instances of jaundice were seen in this series The alkaline phosphatase evel was surprisingly low, even in the patients in cases 3 and 4, in whom there were large hepatic lesions (an interesting contrast to sarcoidosis) The serum gamma globulin level was elevated above 1 5 gm per 100 cc in six cases, and in these six the results of he flocculation tests were grossly abnormal The owest gamma globulin level was 1 18 gm per 100 cc (case 5)

Diagnosis

The following features in various combinations are judged to be reasons for considering the diagnosis of primary miliary tuberculosis of the liver (1) pyrexia of unknown origin, (2) hepatomegaly, not necessarily tender, (3) splenomegaly, (4) episodes of arthralgia, fever, or skin eruptions, (5) a "full" abdomen, contrasting with wasting elsewhere, (6) ascites with protein content above 4 gm per 100 cc, (7) unexplained moderate anemia and leukopenia, (8) unexplained elevation of the serum gamma globulin level, especially with abnormal flocculation tests, and (9) a positive reaction to the Mantoux test These findings assume more significance if the patient is a Negro, or if there has been unusual exposure to alcohol or to tuberculosis

Liver Biopsy—If it is impossible to exclude primary miliary tuberculosis of the liver as a diagnostic possibility, a liver biopsy is indicated This may be performed without delay if there are no contraindications It is, however, important to realize that it is not essential to perform liver biopsy before starting therapy, since recognizable tubercles remain in the liver for weeks after successful therapy has started, as in cases 5, 6, and 7 Therefore, if the patient is deemed too ill or there are other contraindications, specific therapy may be commenced without delay and liver biopsy performed when the patient has improved sufficiently, even two or three weeks later If the tubercles of tuberculosis are demonstrated in the biopsy, the diagnosis is made If the granulomas are nonspecific, they must be interpreted in the light of the clinical picture and of the response to antituberculosis therapy

We have used the modification of the Gillman instrument already described by one of us [8] for liver biopsy This instrument obtains larger specimens than the Vim-Silverman needle without added risk, and the specimens are in better condition than those obtained by the more complicated Iversen-Roholm technique [9] A specific advantage of this instrument in hepatic tuberculosis is that macroscopic examination of the biopsy specimen is facilitated, and the presence of tubercles in the specimen can be confirmed at the bedside by simple inspection, since they are brightly translucent [10]

There were no complications from liver biopsy in this series Indeed, considering that these patients are often seriously ill, liver biopsy seems to be a remarkably safe procedure in this condition

Treatment and Prognosis

Isoniazid and aminosalicylic acid are now given to every patient In more serious cases, streptomycin is also given, and, if the prognosis appears to be grave, steroid therapy is also instituted Our initial dosage for isoniazid is 6 to 10 mg per kilogram of body weight daily, depending on the severity of the case A typical schedule for the most severe case would be as follows isoniazid, 10 mg per kilogram daily until the patient is afebrile, then 6 mg per kilogram daily for three weeks, and finally 4 mg per kilogram daily until he is considered cured, which would never be less than six months, and usually closer to one year, aminosalicylic acid, 12 gm daily by mouth, throughout the course of treatment, and streptomycin, 2 gm daily until the patient is afebrile and then 1 gm daily for three weeks Pyridoxine, 50 mg twice a day, is given to alcoholics on isoniazid therapy and to all patients receiving the higher dosage of isoniazid, in order to prevent peripheral neuritis If cortisone acetate or corticotropin is used, its use is discontinued as soon as the clinical situation allows, in order to avoid complications such as hemorrhage or secondary infection, both of which we have seen in the steroid therapy of miliary tuberculosis

We are not qualified to discuss the duration of therapy We do, however, feel that one should not be misled by the impressive efficacy of therapy or by the absence of early relapse or recurrence Prolonged therapy and rigid follow-up must be practiced until more is learned of the prognosis of this condition

In our experience, response to therapy was remarkably good, and all eight adequately treated patients made a full and uneventful recovery (this excludes the patient in case 4, whose therapy started only four days before death) The patient's fever disappeared within three days in case 10, but usually a week was necessary, and occasionally a longer time Thus one should beware of interpreting the lack of response to a brief course of therapy as an indication of the nontuberculous nature of the illness (as was done in case 8) Rapid clinical improvement was the rule, except in case 7, where biopsy revealed considerable fatty infiltration of the liver in addition to the tuberculosis

Follow-up has not been attempted in the present group, partly because of the problems inherent in alcoholic subjects and partly because most of the patients were eventually referred to the local tuberculosis clinics The patient in case 8, however, was extremely fit 30 months after starting therapy

Comment

In primary miliary tuberculosis of the liver, the tuberculous process remains confined to the liver for a varying time, apart from lymph node involvement Thus, in case 1, the patient died before the lungs or other organs were affected, but there was terminal spread to the lungs and brain in case 2, to the lungs in case 3, and to the meninges in case 4 Before effective therapy was instituted, there was presumptive spread to the bone marrow in case 6 It seems probable that in the past many cases of primary miliary tuberculosis of the liver were regarded as examples of generalized hematogenous tuberculosis, since the diagnosis was usually not made until either miliary tuberculosis of the lungs had appeared or autopsy was performed, when other organs were usually involved Certainly the patients in cases 2, 3 4, and 6 could not have been included in this series had they first been seen after the extrahepatic spread had occurred Similarly we have excluded from this series an equal number of cases which we regard as instances of primary miliary tuberculosis of the liver but in which the patients had important extrahepatic foci when they were first seen

In the nonfatal cases, however, one cannot be certain that the miliary tuberculosis was confined to the liver, although it is true that there was no miliary involvement of the lungs or meninges Moreover, one cannot exclude occult foci such as genital tuberculosis in the female In that case, it may be asked why such emphasis is placed upon the hepatic involvement The answers are that, firstly, the hepatic infection is often the only one that can be suspected clinically, secondly, the hepatic involvement may be considered to be of major importance merely because of the massiveness of the tuberculous process within the liver, as contrasted with the paucity of findings elsewhere, and also because liver biopsy may show a dozen tubercles in a single section of a specimen measuring 20 mm long and 1 5 mm wide, thirdly, the liver is the only place where the tubercles may be easily demonstrated, and, fourthly, emphasis on the hepatic predominance in this syndrome has led to the diagnosis being considered and established at an early stage in the last seven cases that we have encountered

The incidence of primary miliary tuberculosis of the liver in our experience is much greater than a survey of the literature would indicate, even though Cook County Hospital is admittedly a large hospital, with some 3,200 beds One must, however, bear in mind that at least another dozen cases of a similar nature have been excluded from this series because the patients had important extrahepatic lesions when first seen, such as tuberculous meningitis, bilateral hilar lymphadenopathy, pleural effusions without lesions of the lung parenchyma, arthritis, tuberculosis of vertebra (Pott's disease), epididymitis, hypersplenism, and cecal ulceration

Etiology—There seems little doubt that primary miliary tuberculosis of the liver is a hematogenous condition of the liver, and therefore that the infection reaches the liver either by the portal vein or the hepatic artery In most cases, even at autopsy, it is difficult or impossible to decide which of these two routes was involved, although Warthin [2b] described a case in which a caseating lymph node was ulcerating into the portal vein The enlargement of the spleen in many cases necessitates some further explanation, as does the case described by Hickling,[11] in which there was miliary tuberculosis of the spleen without involvement of the liver Such cases make it necessary to consider the possibilities of a caseating node invading the hepatic artery, which would produce pure hepatic tuberculosis, or invading the splenic artery, which would cause primary involvement of the spleen, and perhaps later involvement of the liver via the splenic vein The presence of a caseous or calcified node in the para-aortic or portal area in several of our cases makes it probable that these were the disseminating foci, they in turn having risen either from a primary abdominal infection or, more likely, from an intestinal lesion secondary to a primary pulmonary infection

There was involvement of the abdominal and mediastinal lymph nodes in all four of the patients on whom an autopsy was performed, and there were enlarged external lymph nodes at some stage in the patients in cases 4, 7, 8, and 9 It seems reasonable to suppose that after the activation of the lymph node that has led to hematogenous dissemination to the liver there will be regional lymphatic spread, generally in a cephalad direction, to the para-aortic lymph nodes in the abdomen and thorax

Our group of cases shows some predilection of this condition for males (8 out of 12 cases) and alcoholics (6 out of 12) Amebic liver abscess shows a similar marked predilection for males, and it has frequently been suggested that masculine intemperance is the reason One is tempted to suggest that a similar process may be responsible for the sex distribution in our cases The fact that 9 of the 10 patients with this condition seen at Cook County Hospital were Negroes may also be significant, since less than 50% of the hospital population is Negro, the reason, however, for this racial predominance is probably a complex matter involving racial immunology, social conditions, exposure to tuberculosis, and other factors

Another possible etiological factor may be childbirth Thus, the patient in case 9 had had several inconsequential episodes of cervical lymphadenitis, but, after childbirth, she developed generalized symptoms and rapidly became extremely ill with primary miliary tuberculosis of the liver A similar case is reported by Solomon and Doran,[12] whose patient developed miliary tuberculosis of the liver and spleen after childbirth The spleen, weighing 1,240 gm, was removed at laparotomy, when the liver was also seen to be studded with tubercles, and the patient rapidly recovered

Treatment—Bunn [13] reported that 60% of his patients with miliary tuberculosis who were treated with streptomycin alone developed tuberculous meningitis, a complication that greatly increases the mortality rate, and Lawson and co-workers [14] found that tuberculous meningitis was a less common complication of miliary tuberculosis treated with isoniazid alone than with streptomycin alone The reason for this protective action of isoniazid is presumably its better penetration of the blood-brain barrier Thus Goodman and Gilman [15] state that "most studies indicate that streptomycin enters the cerebrospinal fluid slowly and to a very limited extent even after repeated large parenteral doses in the absence of meningitis" In contrast, Elmendorf and associates [16] demonstrated that appreciable concentration of isoniazid appeared in the cerebrospinal fluid of patients without tuberculous meningitis, as well as of those with meningitis We therefore now use isoniazid and aminosalicylic acid initially in all cases of primary miliary tuberculosis of the liver, with the addition of streptomycin in the more seriously ill patients We have some impression that, apart from its action in preventing tuberculous meningitis, isoniazid is more effective than streptomycin, although two of our patients responded very rapidly to streptomycin (cases 2 and 10) The condition of the patient in case 7, however, continued to deteriorate with use of streptomycin, 1 gm daily, with aminosalicylic acid for 19 days, she then improved dramatically when placed on isoniazid therapy and became afebrile in 14 days, although the dosage of isoniazid was only 100 mg twice a day Again, no objective or subjective improvement was obtained with five days of therapeutic trial of streptomycin in case 8 although later isoniazid (with streptomycin) was dramatically effective These experiences parallel that of Munro and Lees[17] their patient's condition deteriorated and the patient became semimoribund over a period of six weeks while on therapy with streptomycin, 1 5 gm daily, and aminosalicylic acid, she was then given 8 mg of isoniazid per kilogram of body weight daily and a remarkably rapid improvement ensued

If, in fact, isoniazid is more effective than streptomycin in the treatment of primary miliary tuberculosis of the liver, one may speculate that the difference may be explained partly by the method of administration Streptomycin is given parenterally, enters the blood stream slowly, and finally reaches the liver in a greatly diluted state Isoniazid, on the other hand is given orally and passes directly to the liver along the portal vein in a comparatively concentrated form With so few cases, however, we naturally do not make any definite conclusion but merely record a clinical impression Any difference could be explained equally well by relative resistance of the bacilli to streptomycin Since no organisms were cultured, this possibility cannot be excluded

Summary

The clinical entity of primary miliary tuberculosis of the liver is not rare The 12 cases presented were encountered over a period of four years Diagnosis was readily established by liver biopsy The response to treatment, especially with isoniazid, is often dramatic All eight of our adequately treated patients recovered without sequelae

Tuberculin Skin Test —The information secured by tuberculin tests is of value to the physician Knowledge of the prevalence of sensitivity to tuberculin and, in most areas, to fungus antigens would appear basic to the diagnosis of pulmonary illness in any area, for it is impossible to evaluate a chest x-ray properly without knowledge of the skin test reactions Also, the knowledge of previous tuberculin tests is indispensable in evaluating a newly found positive tuberculin test This will be especially true if in the future the preventive treatment of tuberculin converters is accepted as a desirable procedure Tuberculin testing is of value to the individual, especially to those who have a morbid fear of tuberculosis With the low prevalence of tuberculin sensitivity it is extremely reassuring to be able to tell so many patients that they do not have and have never had tuberculosis This assurance can be given only through the use of tuberculin tests It would appear desirable to extend the use of tuberculin testing throughout larger areas of the country —M L Furcolow, M D, F A P H A, On the Usefulness of the Tuberculin Skin Test, *American Journal of Public Health,* September, 1956

SARCOIDOSIS AND PREGNANCY

Robert L. Mayock, M.D., Robert D. Sullivan, M.D., Roy R. Greening, M.D.
and
Ralph Jones Jr., M.D., Philadelphia

• *In following the course of 10 patients with sarcoidosis through 16 pregnancies, it was observed that pregnancy appears to have an ameliorating effect on sarcoidosis during the prenatal period but that this benefit is frequently lost after delivery. All the patients tolerated pregnancy well, however, there were two abnormalities of pregnancy and three fetal abnormalities noted in the 16 pregnancies. The observed improvement of the sarcoidosis during pregnancy might constitute evidence against tuberculosis being the etiology of sarcoidosis, since pregnancy does not improve, and may even aggravate, tuberculosis. It is possible that improvement of sarcoidosis during pregnancy is due to the increase in production of corticoids by the adrenal glands during gestation.*

The occurrence of pregnancy in women with sarcoidosis has seldom been reported.[1] Evaluation of the effects of these conditions on each other is important both for the academic desire of giving a better description and understanding of the disease process and for the practical necessity of forming valid bases for prognosis and management.

In the medical literature, we have found reports of 11 patients with sarcoidosis observed during the course of 13 pregnancies, and in some of the reports the data on the patients before and after pregnancy were sparse. In the majority of reported cases, the authors concluded that pregnancy had no effect on sarcoidosis and that no abnormalities of pregnancy occurred. In 1951 Berman[1f] and later Aikens and Beckwith[1g] each described a patient in whom the lesions of sarcoidosis improved during pregnancy and suggested that pregnancy may exert a favorable effect on the disease process.

During the past eight years, we have observed the course of 16 pregnancies in 10 patients with sarcoidosis. Our observations suggest that pregnancy has a beneficial effect on sarcoidosis that is frequently lost after delivery. The purpose of this report is to describe the changes observed in the manifestations of *sarcoidosis during pregnancy and to evaluate possible* effects of this disease on pregnancy.

Method of Study

Seven patients were followed throughout the course of one pregnancy each, two patients were followed through two successive pregnancies, and one patient was followed through five pregnancies. The diagnosis of sarcoidosis was established in every patient on the basis of typical clinical findings and the demonstration of histological lesions in biopsy specimens. All patients were studied to eliminate the possible existence of tuberculosis and the deep fungus diseases. The known duration of the disease prior to the time of pregnancy varied in the patients in our study from 4 months to 10 years. In all cases there was a period of observation of the natural course of the disease prior to pregnancy. All patients were followed in the clinic of the Hospital of the University of Pennsylvania throughout the course of pregnancy, and all have been observed for 10 months or more after delivery. The pertinent clinical data in these cases are summarized in table 1.

Serum protein concentration was measured by the biuret method.[2] Albumin and globulin were separated by the sulfate-sulfite technique described by Reinhold and co-workers.[3] Serum globulin was fractionated into the euglobulin and pseudoglobulin fractions by a similar technique with use of a 16.8% solution of sodium sulfate and a 1.7% solution of sodium sulfite. Pooled serum that had been subjected to electrophoretic analysis was used as a standard for each analysis. The protein fractions obtained by chemical separation compared closely with and can be related to those obtained by electrophoresis.[4] By the use of this method, the euglobulin was found to consist of the beta and gamma globulins.

Serial chest roentgenograms were obtained in all patients before, during, and after pregnancy. Because of the difficulty of interpreting changes in chest roentgenograms, the films were reviewed by four traine observers who had no knowledge of the relation o the roentgenograms to the time of pregnancy. N change was considered to be significant, unless it wa the unanimous opinion of all four observers tha unequivocal change was present.

Effects of Pregnancy on Sarcoidosis

Table 2 summarizes the changes in the abnorma findings during and subsequent to each pregnancy.

Changes During Pregnancy.—In eight of the patients studied, there was improvement in some of th manifestations of sarcoidosis during pregnancy. I two patients (cases 7 and 8), each of whom wa observed through a single pregnancy, there was n detectable change in single manifestations. The patient in case 7 had parenchymal lung lesions, and th patient in case 8 had hilar adenopathy. Only on patient (case 9) developed evidence of progressio of the disease, consisting of new skin lesions on bot legs, during the eighth month of pregnancy. Complet regression of the disease occurred in only one patien (case 3). This patient had peripheral lymphadenopa

Mayock, Sullivan, and Jones) and the Department of Radiology (Dr. Greening), Hospital of the University of Pennsylvania. Dr. Sullivan is now at the Veterans Administration Hospital, New York. Dr. Jones is now at the Department of Medicine, Jackson Memorial Hospital, Miami, Fla.

TABLE 1—*Summary of Clinical Data in Ten Patients with Sarcoidosis During Pregnancy*

Case No	Age at First Pregnancy Yr	No of Pregnancies Since Diagnosis	Biopsy Site	Duration of Disease Before Pregnancy	Involvement	Period of Observation After Last Delivery
1	23	2	Lymph node	8 mo	Eyes lungs lymph nodes blood serum proteins	2¼ yr
2	26	1	Tonsil and skin	2 yr	Tonsils lungs blood serum proteins skin	4¼ yr
3	26	5	Bone	4 mo	Lungs bone lymph nodes	17 mo
4	21	1	Lymph node	2 yr	Parotid glands lymph nodes lungs blood serum proteins	1 yr
5	32	1	Lymph node	8 yr	Eyes lungs lymph nodes	4 yr
6	28	1	Lymph node	9 yr	Lymph nodes lungs serum proteins	2 yr
7	31	1	Lymph node	4 yr	Lungs lymph nodes	2¼ yr
8	26	1	Parotid gland	14 mo	Lungs lymph nodes parotid	10 mo
9	22	1	Lymph node	1 yr	Eyes liver spleen lymph nodes joints blood skin	11 mo
10	16	2	Lymph node	10 yr	Joints lymph nodes lungs liver heart	1 yr

hy and extensive pulmonary lesions, both of which disappeared completely during her first pregnancy Three months after the delivery the lymphadenopathy recurred, but her chest roentgenogram remained normal The lymphadenopathy regressed during each of the two subsequent pregnancies and recurred each time within a few months after delivery Prior to, during, and subsequent to her last two pregnancies, no abnormalities were noted

Changes After Delivery—After delivery, the abnormal findings returned in about one-half of the patients (table 3) Within several months after delivery, four patients (cases 2, 4, 8, and 9) developed new manifestations of sarcoidosis that had not been previously noted These consisted of multiple skin lesions in case 2, leukopenia in case 4, parotid swelling in case 8, and hepatosplenomegaly with hemolytic anemia in case 9

All of the patients tolerated pregnancy well and, in some instances, considerably better than we had anticipated For example, one patient (case 6) had such advanced pulmonary changes before and at the onset of pregnancy (fig 1) that she became dyspneic on the slightest exertion Termination of the pregnancy was seriously considered on three occasions because of fear for the mother's safety, but her exercise tolerance actually increased during pregnancy and she delivered spontaneously at term without difficulty

TABLE 2—*Effects of Pregnancy on the Objective Findings in Ten Patients with Sarcoidosis*

			Abnormal Findings During Pregnancy			Abnormal Findings After Delivery

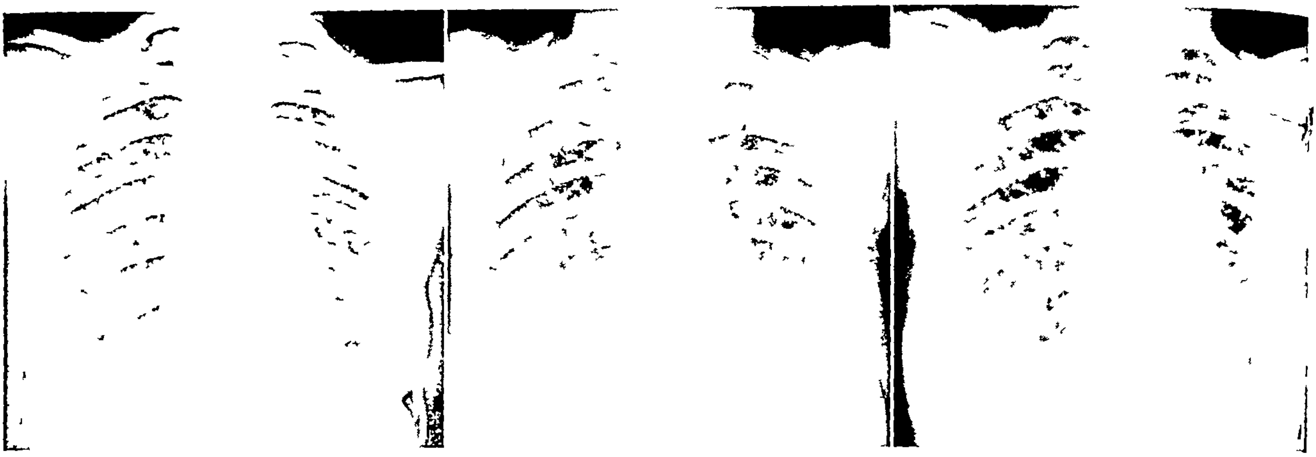

Fig 1 —Roentgenographic changes in patient in case 6 *Left* taken five months before pregnancy showing nodular disease scattered throughout both lung fields, combined with hilar and mediastinal adenopathy *Center,* taken at eight months gestation illustrating regression of parenchymal and hilar disease *Right,* taken two and one-half months after delivery showing return of parenchymal disease and hilar adenopathy

Changes in Specific Manifestations—The changes observed in the objective manifestations of sarcoidosis are summarized in table 3

Peripheral Lymph Nodes Significant enlargement of peripheral lymph nodes was present in patients before four pregnancies The nodes became normal in size during pregnancy in all four instances In one patient the lymph nodes remained normal during 18-months observation after delivery In the other three instances the peripheral nodes enlarged to the prepregnancy size within three months after delivery

Pulmonary Changes Hilar or mediastinal lymphadenopathy or both was observed before pregnancy on eight occasions, and serial chest x-rays revealed evidence of improvement in six instances during pregnancy No change was observed during two pregnancies The improvement was maintained in three of the six instances after delivery In the other three instances, the hilar and mediastinal nodes enlarged to their previous size four to six months after delivery Lesions of the pulmonary parenchyma were present prior to pregnancy on eight occasions, and some degree of clearing resulted in seven of these instances In one patient the condition was unchanged, and in none was it worse In three of the seven instances of improvement, the lesions became worse again after delivery

Uveitis Three patients had chronic indolent uveitis of long duration that did not change during the course of four pregnancies

Blood Changes Prior to four pregnancies, the white blood cell count was less than 4,000 cells per cubic millimeter In two patients, the white blood cell count returned to normal levels during pregnancy and fell to abnormal levels again within three months after delivery Leukopenia persisted throughout pregnancy in the other two instances One patient (case 1) had a normocytic hypochromic anemia, with a hemoglobin level of 46% In this patient, the red blood cell count and hemoglobin level increased to normal during pregnancy and remained normal after delivery

Serum Protein Levels The concentrations of total serum protein and of the various fractions were determined at frequent intervals before, during, and after pregnancy in four patients The changes observed are shown in figure 2 The total serum prot concentration was at the upper limits of normal or above in all of these patients before pregnancy The concentration of total serum protein decreased in all patients during gestation and increased after delivery The concentration of serum albumin decreased in

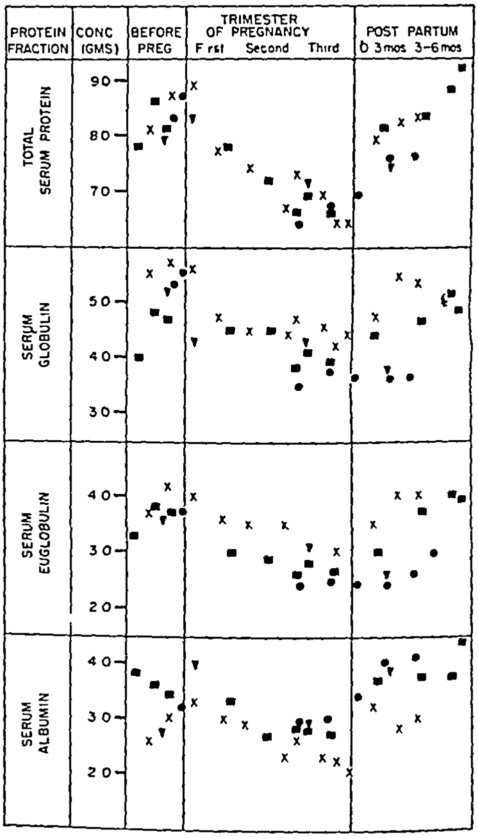

Fig 2 —Changes that occurred in the serum proteins during and after pregnancy in patients with sarcoidosis Values for determinations performed on each of the four patients with serum protein abnormalities are indicated by a different symbol such as x There was a fall in total serum protein, serum globulin serum euglobulin, and serum albumin levels These changes are compared to those occurring in normal pregnancy in figure 3

three patients and increased slightly in a fourth patient. After delivery there was an increase in the serum albumin concentration in all four patients.

The serum globulin concentration was abnormally high before conception in four of the patients. In these patients the serum globulin concentration decreased during gestation. In two of the four patients the globulin concentration increased to abnormal levels after delivery, in the other patients the globulin concentration remained normal for six months after delivery.

The changes in concentration of the euglobulin fraction paralleled the changes in total globulin concentration. The pseudoglobulin concentration decreased somewhat during pregnancy in two patients and was unchanged in the other two.

Coryell and co-workers[5] have studied the effect of pregnancy on the concentration of plasma protein fractions, determined by electrophoresis, in the normal female and have demonstrated that during gestation the total serum protein and the serum albumin concentrations decrease while the serum globulin concentration increases slightly. Hence the significance of the changes observed in patients with sarcoidosis can be appreciated only by comparison with the changes that occur in normal women during pregnancy. In figure 3 the changes that occurred in patients with sarcoidosis are compared with the changes observed in normal women by Coryell and co-workers. In the patients with sarcoidosis, the decrease in total protein concentration was greater than the average decrease that occurred in normal women. The decrease in serum albumin levels in patients with sarcoidosis was less than the average decrease in serum albumin levels observed by Coryell and co-workers[5] in normal women. The serum globulin and euglobulin concentrations decreased progressively in the patient with sarcoidosis, whereas the concentrations of both fractions increased slightly during pregnancy in normal women.

In our patients with sarcoidosis the concentrations of the serum protein fractions tended to return to normal during pregnancy. In some patients this improvement persisted after delivery. In others the abnormality returned fairly promptly after delivery.

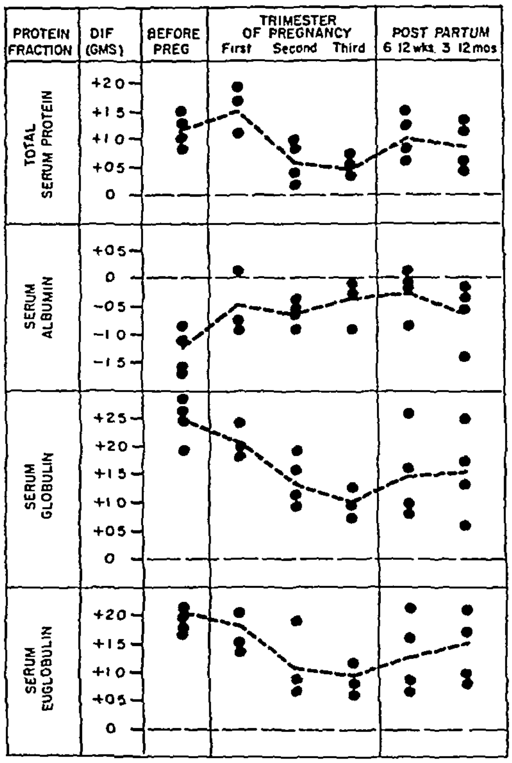

Fig 3.—Average value for total serum proteins and the protein fractions during pregnancy in normal women[5] were used as normal and plotted as the zero lines. Subtraction of the values found in patients with sarcoidosis in the present study from the values found in normal patients yielded the data plotted above. The dotted line is the mean for the plotted values. During pregnancy the serum proteins of patients with sarcoidosis returned toward normal (zero line).

Skin Lesions. Skin lesions were not noted prior to pregnancy in any individual. In the eighth month of pregnancy, the patient in case 9 developed bilateral lesions of the legs that proved to be due to sarcoidosis on biopsy. This was the only instance in which a patient became worse during pregnancy. Within three months after delivery, one patient developed skin lesions not previously noted.

Symptoms. The only subjective manifestations analyzed were cough and shortness of breath. These symptoms were present in five patients and in all five improved during pregnancy. It is noteworthy that

Table 3.—*Summary of Effects of Pregnancy on Objective Findings in Ten Patients with Sarcoidosis*

Conditions	No of Pregnancies	Status of Sarcoidosis During Pregnancy: Unchanged	Improved	New Involvement	Status of Sarcoidosis After Delivery: Remained Improved	Relapsed	New Involvement
Peripheral lymphadenopathy	4		4		1	3	
Pulmonary changes							
Hilar adenopathy	8	2	6		3	3	
Parenchymal lesions of lung	8	1	7		4	3	
Chronic uveitis	4	4					
Blood changes							
Leukopenia	4	2	2			2	1*
Anemia	1		1		1		1*
Serum protein abnormality							
Hypoalbuminemia	3		3		2	1	
Hyperglobulinemia	4		4		2	2	
Skin lesions				1*			1*
Parotid enlargement							1*
Heptosplenomegaly							1*

Patients with new involvements not included in column No of Pregnancies improvement in dyspnea occurred, since this is the reverse of the usual shortness of breath that develops in uncomplicated pregnancy After delivery two patients had a return of symptoms, while in three patients improvement was maintained during the postpartum period of observation

Possible Effects of Sarcoidosis on Pregnancy

Abnormalities of Pregnancy.—Two abnormalities of pregnancy were encountered premature delivery at 32 weeks in one patient, and stillbirth at 34 weeks in another A macerated fetus approximately five months of age was delivered No abortions occurred There was one twin pregnancy that was normal in all respects The placenta was examined grossly after delivery in every case and was found to be normal

Abnormalities of the Fetus.—Three fetal abnormalities were observed One infant with a supernumerary digit on each hand (case 1), one with six digits on the left foot (case 8), and a third infant (case 9) with congenital heart disease who died at the age of 6 months The autopsy findings in this child were cor triloculare, atresia of the pulmonary artery, overriding of the aorta and pulmonary artery, and patent ductus arteriosus

Comment

While we are well aware of the difficulty in relating a change in the manifestations of sarcoidosis to the effect of a specific agent or event, we believe that the results of this study indicate that pregnancy usually exerts an ameliorating effect on the disease process of sarcoidosis In the study of the natural history of a chronic disease, the effects of the major hormonal changes, such as occur in adolescence, pregnancy, and menopause, provide important information They add to the description of the disease process and thus avoid the ascribing of changes, resulting from these natural events, to changes in therapy or management In addition, such studies in other diseases have formed a background for the formulation of theories of etiology[6]

A possible etiology for sarcoidosis is still considered to be tuberculosis The available evidence as summarized by Rich[7] indicates that during pregnancy tuberculosis does not improve and is probably aggravated The improvement observed by us in sarcoidosis during pregnancy constitutes evidence against tuberculosis as the etiology of this disease, unless the ancient argument of the presence of a 'different' kind of tuberculosis is used

Improvement during pregnancy with subsequent relapse after delivery has been reported in patients with rheumatoid arthritis, psoriasis, fibrositis, asthma, hay fever, and intermittent hydrarthrosis[6] The analogous response of sarcoidosis during pregnancy suggests a relationship to these diseases of hypersensitivity but offers no direct proof that they are kindred conditions However, when one considers that sarcoidosis is often associated with eosinophilia,[8] disturbed serum protein patterns,[8] clinical response to steroid therapy,[9] and serologic hyperreactivity,[10] the hypothesis that sarcoidosis may be related to hypersensitivity appears more attractive

After delivery, new manifestations were noted in four patients These may have been due to simple progression of the disease but more likely represented a so-called rebound relapse, previously described after steroid therapy[11] The mechanism of these effects is unknown Because administration of large dosages of adrenal steroids usually produces regression of the active lesions of sarcoidosis,[9] it is possible that improvement in the disease during pregnancy is due to the increase in production of corticoids by the adrenal glands during gestation[12]

Because sarcoidosis often produces extensive changes, particularly in the chest roentgenogram, the question of the desirability of avoiding or of interrupting pregnancy is often raised in these patients The fact that active tuberculosis is affected unfavorably by pregnancy has led those who believe that sarcoidosis is due to an altered reaction to the tubercle bacillus to advocate therapeutic abortion in this disease Our studies and the evidence that is available from the literature suggest that therapeutic abortion should rarely be necessary in patients with sarcoidosis

The abnormalities of pregnancy and the fetus are worthy of comment The two miscarriages and three congenital abnormalities in 16 pregnancies make further observations of this relationship important There was no family history of congenital abnormalities in any of the three cases in which such abnormalities were present A review of the previously reported cases[1] disclosed that the 11 patients delivered 12 normal-term infants during the period of observation One stillbirth occurred, apparently due to a transverse position of the fetus No abortions, except one performed therapeutically, occurred in those patients

Summary and Conclusions

In 10 patients with sarcoidosis the course of 16 pregnancies has been observed Multiple manifestations of the disease were usually present, and in 8 of the 10 patients improvement of some of the manifestations occurred during the period of pregnancy In two patients no change occurred Except for the development of skin lesions of the leg in one patient, no evidence of progression of the disease during pregnancy was noted Relapse frequently occurred after delivery, and four patients developed new manifestations in the immediate postpartum period Two premature deliveries with one stillbirth occurred, and three congenital abnormalities were noted in 16 pregnancies

These observations indicate that pregnancy usually has a beneficial effect on sarcoidosis that is often lost after delivery The possible deleterious effect of sarcoidosis on pregnancy and on the fetus is worthy of further study

CLINICAL RESULTS WITH VIADRIL IN ONE THOUSAND CASES

F Paul Ansbro, M D , Albert E Blundell, M D , Joseph C Sweeney Jr , M D , Brooklyn, N Y
and
John W Pillion, M D , Lawrence, Mass

• Viadril, a synthetic derivative of pregnanedione and succinic acid, was used as the primary anesthetic agent in 1,000 surgical operations The customary premedication was given one hour before the induction A total of 1 to 1 5 Gm of Viadril was given intravenously, generally as a 0 5% solution in 5% dextrose and water, over a period of about four minutes It took effect in about three minutes The degree of anesthesia so produced was not sufficient for intubation and maintenance without the aid of muscle relaxants and inhalation anesthetics There were no deaths attributable to the Viadril, but it had many unfavorable circulatory and respiratory effects Its obtunding effect on laryngeal and pharyngeal reflexes, however, facilitated the insertion of an airway, and this suggests its utilization in surgery of the head and neck It also indicates that further exploration of the anesthetic properties of other steroid compounds is desirable

We have administered Viadril (21-hydroxypregnanedione sodium succinate) intravenously in 1,000 cases and are presenting our observations as to the value or practicability of the drug as an anesthetic agent or as an adjunct to such other forms of anesthesia as regional, spinal, and general The literature concerning the anesthetic activity of the steroids was reviewed before starting this study, and there was evidence available that the chosen steroid (Viadril) had certain properties that could possibly be utilized by the anesthesiologist However, as the series grew in number, the facts as presented in the paper by Howland and associates [1] became quite evident

History

New families of drugs have from time to time been introduced into the field of anesthesiology, either as primary anesthetic agents or for use in conjunction with existing modalities of anesthesia One need hardly mention such momentous advances as the introduction of procaine to spinal anesthesia or of curare to general anesthesia Recently another family of compounds was introduced to anesthesia in the form of steroids which are capable of producing an anesthetic state" without any manifestation of hormonal activity

In 1941 Hans Selye [2] observed that steroid hormones would cause deep anesthesia in various experimental animals if they were administered intra-abdominally or intravenously in large amounts Later observations by Selye and co-workers [3] with some 75 steroid compounds were carried out In partially hepatectomized rats [4] major abdominal surgery could be carried out under "steroid anesthesia' Desoxycorticosterone acetate and progesterone were found to have the greatest degree of anesthetic activity

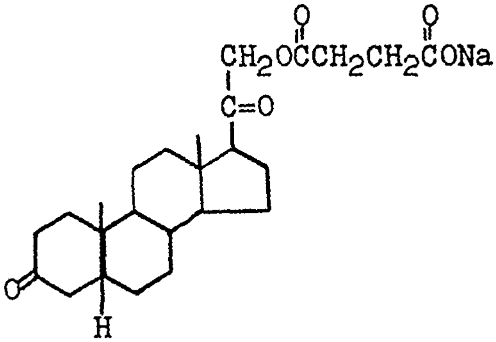
In conjunction with the above observations, Selye [5] showed that resistance to the anesthetic effect of steroid hormones can be acquired by the organism and

---

Read before the Section on Anesthesiology at the 105th Annual Meeting of the American Medical Association Chicago June 13, 1956 that it is an adaptation to the pharmacological action is such, rather than to a certain chemical compound possessing this pharmacological activity Another observation[6] was that the anesthetic activity increased in those animals whose central nervous system was least developed From these facts Selye introduced a fish bioassay for anesthetic steroid activity Selye concluded that steroids represented a new group of anesthetics, and indeed even some steroids not known to exhibit hormonal properties proved to be endowed with a pronounced narcotic effect

Firson, Carr, and Krantz[7] disputed the use of the word anesthesia as applied to the cortical depression produced by the steroid hormones, though it produces a similar pattern to the barbiturates

With the basic work of Selye in mind, Laubach, P'an, and Rudel[8] tested a large number of water-soluble steroids in regard to anesthetic activity, toxicity, and hormonal activity and from their work evolved Viadril as the one with the most potent anesthetic property combined with low toxicity and no demonstrable hormonal activity This compound was first used in man by Gordon and associates[9] and later clinical observations were made by Murphy[10] and his group at the University of California with rather promising results A recent report by Howland and associates[1] has modified some of the observations of the former group



Structural formula of Viadril (21-hydroxypregnanedione sodium succinate)

Chemistry

Viadril is synthesized by esterifying 21-hydroxypregnanedione with one of the two carboxyl groups of succinic acid and reacting the resulting ester with sodium carbonate to produce the acid salt The resulting compound is readily soluble in either isotonic sodium chloride solution or 5% dextrose in water and exists in its ionic state when in solution Examination of the chemical formula shows that Viadril may be considered to be the sodium salt of a lipid fatty acid, which acts as an irritant and in some cases as a sclerosing agent in the vein into which it is flowing This explains the complaint of pain and burning during the infusion of Viadril and the resulting phlebitis and thrombosis

The infused Viadril is hydrolyzed into its component parts, 21-hydroxypregnanedione and sodium succinate, the latter of which plays no part in the production of anesthesia The ketone oxygen on the third carbon atom of the steroid molecule is then reduced to a hydroxy group This also exhibits anesthetic properties It has been shown, however, that this property exists only if the hydroxy group on the third carbon atom and the hydrogen on the fifth carbon atom are optically on the same side of the steroid molecule (Tomkins[11]) 21-Hydroxypregnanedione is excreted in the urine in its reduced form after being conjugated with glycuronic acid (Venning and Browne[12])

The series was initiated with the use of Viadril as the primary anesthetic agent in major operations (522 cases) Later we used it as an adjunct to other modalities (particularly epidural block) as a sedative or hypnotic (352 cases) The remainder of the series were cases of minor nature, such as dilation and curettage, and cystoscopy (126 cases)

Observations

There were no deaths attributable either directly or indirectly to the anesthetic agent In 522 cases Viadril was used as the primary agent, by which it is meant that Viadril was used as the agent of induction of anesthesia Nearly all patients in this series were intubated with the aid of a muscle relaxant (succinylcholine), and surgical relaxation was maintained with tubocurarine and nitrous oxide-oxygen supplementation In a very few instances efforts were made to intubate the trachea and to conduct the entire surgical procedure with Viadril alone It soon became apparent that this was not consistently possible Intubation without succinylcholine was usually successful, but too frequent "bucking rendered it inadvisable Lack of adequate relaxation during surgery even with nitrous oxide-oxygen supplementation made the routine use of tubocurarine imperative

Following is a loose breakdown of the types of major surgery performed with Viadril as the primary agent thyroidectomy, 52 cases, upper abdominal (gallbladder, gastrectomy), 156, lower abdominal (hysterectomy, appendectomy), 128, thoracic (thoracoplasty, pulmonary resections), 12, and others (intestinal resections, pelvic gynecologic, kidney and bladder), 174

In 352 cases Viadril was used as an adjunct to other modalities The breakdown for this series was as follows epidural block, 290 cases, spinal block, 37, and brachial and other peripheral nerve blocks, 25

In the cases listed above, Viadril was used as an hypnotic in place of a barbiturate In this series we found it very useful, particularly as regards the great difference on the laryngeal reflexes when compared with barbiturates

In the 126 cases of minor nature in which Viadril was used, efforts were made to conduct the entire procedure with Viadril alone without supplementation In most of them, however, supplementation with nitrous oxide-oxygen anesthesia was necessary The breakdown for this series was as follows dilation and curettage, 47 cases, cystoscopy, 12, genital (male and female), 38, and extremities, 29

Results

It is pertinent to remark that all the cases were physical status 1 or 2 (no serious physical factors affecting the anesthetic risk) The sexes were about equally divided, and the ages ranged from 15 to 81 years We avoided the use of Viadril in children and in risk C patients (those with one or more serious physical factors affecting the anesthetic risk) Observations were made in regard to the following conditions and effects

Premedication—We employed the usual premedication drugs, morphine or meperidine, atropine or scopolamine, and combinations of the latter with promethazine, in the usual dosage range administered about one hour before anesthesia began We detected no noticeable difference in regard to any of them, with the exception that those patients who had received promethazine instead of an opiate appeared to have less respiratory depression

Amount and Concentration—The vast majority of patients to whom Viadril was administered received a 0 5% solution in 5% dextrose and water A few received a 1% solution, and in no instance did we exceed this concentration The total amount varied from a minimum of 500 mg to a maximum of 1,500 mg The great majority received 1 to 1 5 Gm

Speed of Infusion—The speed of infusion varied between three and nine minutes The great majority of infusions were made within four minutes

Location of Vein Used—Generally we sought a vein in the forearm, which was not located at a joint, for the injection of Viadril Occasionally, however, we had to employ the antecubital vein or one located on the dorsum of the hand

Onset of Hypnosis—The time from the end of infusion to the onset of hypnosis varied with the dose and the speed of infusion The average period was three minutes

Effect on Cardiovascular System—The usual effect on the cardiovascular system was an early but moderate fall in systolic pressure, with a narrowing of the pulse pressure that lasted a variable length of time (5 to 30 minutes) In the group in which 1% solution was employed, there occasionally developed a severe hypotension which responded well to vasopressor drugs Two patients, however, caused concern but finally responded to treatment In one instance hypertension that could not be directly attributed to the effects of the drug was observed postoperatively

There were no severe cardiac arrhythmias noted in this series A tachycardia was present in nearly all cases, which was quite variable in degree, ranging from 10 to 80 beats per minute above the patients' normal pulse rate In some instances extrasystoles were observed to be associated with the tachycardia

Effect of Respiration—We noted the most undesirable features of Viadril in its effect on respiration The respiratory patterns were varied and bizarre In one patient (a woman, aged 29) a tachypnea to 60 respirations per minute was recorded Other respiratory rates varied from 30 to 40 respirations per minute Bradypnea was noted in 26%, with a rate varying from 15 down to 10 respirations per minute The occurrence of apnea was frequent (10%) This lasted from 5 to 25 minutes These patients, of course, received assistance by bag pressure The apnea was in the early phase of the procedures but was not related to the succinylcholine used for intubation In some instances the apnea occurred when succinylcholine was not previously administered All respiratory changes occurred shortly after the infusion of the drug and, except for the one case of severe tachypnea lasting 45 minutes, there was not any cause for alarm Tachypnea in the latter case persisted with downward gradation for five hours, at which time the respiration returned to normal The patient was awake during the last four hours of the persistent tachypnea This patient was operated on again the same evening for the arrest of intra-abdominal hemorrhage with the use of cyclopropane-oxygen There was no evidence of tachypnea with the latter agent

Duration of Anesthesia—The duration of anesthesia, of course, varied with the dose administered The average duration after the administration of 1,500 mg was 1 hour and 25 minutes In occasional cases with this amount there were short-lasting effects (25-35 minutes) In one instance in which the premedication was excessive, unconsciousness persisted for four hours There was, however no complete failure in any case to obtain unconsciousness

Incidence of Complications in Use of Viadril

Respiratory	
Tachypnea—moderate 30-40 respirations per minute	35%
severe 40-60 respirations per minute	0 1%
Bradypnea—10-15 respirations per minute	26%
Apnea	10%
Phlebitis	
Severe—5 cases	0 5%
Phlebitic pain on injection	15%

Phlebitis—In utilizing the 0 5% concentration and rapid infusion there were surprisingly few instances of phlebitis In view of the literature on the subject and the experience of others, we expected more trouble in this regard There were five cases of severe phlebitis in the whole series (0 5%), although many more patients complained of pain on injection (15%) There was no evidence of phlebitis postoperatively in the latter group We feel that the 0 5% concentration and rapid infusion, followed by 50 cc of isotonic solution administered at a rapid rate to "wash out' the vein, has contributed to the decreased incidence of phlebitis in this series

Comment

In 1,000 administrations of Viadril in this study we observed the effects of the drug as an anesthetic agent These effects were most apparent on the cardiovascular and respiratory systems Hypotension was frequent but not excessive and was easily controlled Tachycardia of varying degree was almost constantly present Phlebitis occurred in five cases, although there were many other patients who complained of pain on injection but had no postoperative trouble in this regard The most objectionable effects were on the respiratory system, these showed many bizarre and varied patterns Bradypnea and apnea were frequently encountered, and tachypnea in one case was alarming In all cases the drug produced anesthesia but of uncertain duration It did not produce sufficient anesthesia for surgery in the vast majority of cases and had to be supplemented with inhalation agents Relaxation for intubation and for surgery required the use of muscle relaxants Viadril did not sensitize the pharyngeal reflexes, and we found it most frequently useful as a supplement to regional anesthesia, in which it produced satisfactory unconsciousness and permitted the insertion of an airway without arousing undesirable reflexes The incidence of phlebitis, comparatively speaking, was very low, and we attribute this to the high dilution of the drug and its rapid administration In only one case was recovery prolonged beyond 1 hour 30 minutes, and this was probably due to excessive preanesthetic sedation

Summary and Conclusions

Viadril (21-hydroxypregnanedione sodium succinate) was administered intravenously to 1,000 patients for a variety of surgical procedures Ages ranged from 15 to 81 years A degree of anesthesia was produced in all cases but was not sufficient for intubation and maintenance without the aid of muscle relaxants and inhalation anesthetic agents There were no deaths in the series attributable directly or indirectly to the anesthetic agent

There were many deleterious effects evident on the cardiovascular and respiratory systems Hypotension and tachycardia were present in nearly all cases, and also occasional cardiac irregularities

Phlebitis at site of injection occurred in 0 5% of the cases Bradypnea and apnea were observed frequently, and in one case tachypnea (60 respirations per minute) persisted for five hours The laryngeal and pharyngeal reflexes were obtunded to permit the insertion of an airway in all cases

The steroids show promise as anesthetic agents The steroid used in this series (Viadril) is not recommended for routine use Further work on the steroids may evolve a product that will be more satisfactory The only virtue of Viadril in this study was its effect on the reflexes of the pharynx and larynx In this respect its utility in head and neck surgery may be considered

544 E 43rd St (3) (Dr Ansbro)

The Viadril used in this study was supplied by Chas Pfizer & Company, Inc , Brooklyn, N Y , through H W Rudel, M D

Digitalis Therapy in Children—Digoxin is suggested as the the drug of choice for digitalis therapy in infants and children, primarily because of its rapid dissipation Our studies and experience with digoxin in normal infants as well as in those with heart disease enable us to propose a digitalizing regimen which has proven effective and yet safe in most of the infants who can benefit from digitalis therapy We recommend an initial "digitalizing dose" of 75 μg/kg in 24 hours, orally or intramuscularly One-half or one-third is given first and the remainder in equal portions every 6 to 8 hours If the desired clinical effect is evident, a maintenance dose of 25 μg/kg once daily is administered If, however, the desired clinical effect has not been achieved after the initial "digitalizing dose,' 25 μg/kg should be given under careful clinical and electrocardiographic observation every 6, 8 or 12 hours (depending upon the severity of the failure) until either a satisfactory effect or toxic signs appear The maintenance dose may then be proportionately larger Changes in S-T segment and T wave in the electrocardiogram are not considered signs of toxicity The development of vomiting or the appearance in the electrocardiogram of significant conduction defects, or arrhythmias are indications of digitalis toxicity Relatively large amounts of digoxin may be necessary in some infants both initially and for maintenance in order to obtain maximum benefit from the drug—S O Sapin, M D , E Donoso, M D , and S Blumenthal, M D , Digoxin Dosage in Infants, *Pediatrics,* November, 1956

CLINICAL NOTES

SPUTUM SPECIMENS VERSUS BRONCHIAL ASPIRATES IN DIAGNOSIS OF BRONCHOGENIC CANCER

Doris S Rome, M D
and
Kenneth B Olson, M D, Albany, N Y

A marked increase in the incidence of bronchogenic carcinoma is evident in virtually all reports, and five-year survival rates are less than 5% in most series It has been shown to be possible to suspect the diagnosis of lung cancer in asymptomatic patients by routine roentgenographic examination, and the survival of these patients after pneumonectomy is longer than that of patients with symptoms In a series of cases of bronchogenic carcinoma at the Albany Hospital a diagnosis of pulmonary illness, usually considered to be pneumonia and associated with expectoration, preceded the diagnosis of cancer in 18 1% of cases

Since the cytological examination of sputum specimens for malignant cells is a reliable method of suspecting pulmonary cancer,[1] the use of this method in all adults with expectoration seems indicated Cytological examination of bronchial washings[2] is considered to produce fewer false-positive and false-negative results than examination of sputum Bronchoscopy probably should not be performed without a definite indication such as suspected pulmonary cancer or resistant lung infection, so bronchial aspirates are examined only when patent lung disease is present, Therefore, this examination is a poor screening procedure The availability of sputum makes it a suitable indicator for the early suspicion of pulmonary cancer

It is the purpose of this discussion to evaluate the results of cytological examination of sputum specimens and bronchial aspirates in the diagnosis of bronchogenic cancer In the study reported here, 3,102 specimens of sputum and bronchial aspirates from 1,203 patients were examined cytologically at the Albany Medical Center for the presence of cancer cells A total of 266 patients were ultimately considered to have bronchogenic cancer

Method and Materials

Sputum was obtained by instructing patients to expectorate directly into a jar containing 70% alcohol Bronchial aspirates were placed directly into 95% alcohol In most instances, direct bronchial aspiration sufficed, but in some cases the bronchi were lavaged with saline solution when secretions were not readily available This was not a routine procedure In the laboratory the specimens were centrifuged, and the sediment was smeared on glass slides Smears were stained by the usual Papanicolaou technique,[3] and each slide was studied for a minimum of 10 minutes Slides suspected of indicating cancer were studied for a longer period of time Reports were made according to the Papanicolaou classification, specimens categorized in class 1 and 2 were considered negative those in class 3 suspicious, and those in classes 4 and 5 were regarded as positive for the presence of cancer

In a 37-month period, 3,102 specimens were received from 1,203 patients, an average of 2 5 specimens per patient This includes specimens of bronchial aspirates and sputum and many patients provided material for both examinations Most of the patients were in the Albany Hospital and on the thoracic surgery service, although many specimens were received from patients visiting outpatient clinics and private physicians in the Albany area In many of these patients a suspicion of chronic lung disease possibly carcinoma, already existed Specimens were not obtained from all patients with lung cancer, and, occasionally, when the diagnosis was obvious at bronchoscopy, no specimens were submitted for cytological study

Table 1 —*Pulmonary Status of Patients Whose Sputum Specimens or Bronchial Aspirates Were Examined Cytologically*

Diagnosis	Patients	
	No	%
Negative no tumor	716	59 5
Positive bronchogenic cancer	203	16 9
False negative bronchogenic cancer	63	5 3
False suspicious no tumor	97	8 1
False positive no tumor	10	0 8
Metastatic lesion	46	3 8
Lymphoma	10	0 8
Esophageal tumor	4	0 3
Inadequate specimen	21	1 7
Diagnosis undetermined	33	2 7
Total	1 203	100 0

Results

Table 1 is a summary of the cases in which cytological examination was done In this series there were 266 patients with lung cancer, and in 254 the diagnosis was eventually established by histological examination In the other 12 cases there was strong clinical evidence of lung cancer, 8 of these patients have since died In 203 of the 266 cases (76 3%) positive or suspicious results of the cytological examination were reported These results are presented in more detail in table 2 Cytological results indicated that specimens from 126 patients (47 4%) were definitely positive and that specimens from 77 (28 9%) were suspicious

---

From the Subdepartment of Oncology, Department of Medicine Albany Medical College

Of the 266 patients considered to have lung cancer, in 63 (23.7%) cytological examinations of the specimens of sputum or bronchial aspirates gave negative results. Nearly half of these patients had anaplastic carcinomas and 30% had squamous-cell type of cancer (table 3). If more specimens had been obtained or if more vigorous washing of the bronchial tree had been done at bronchoscopy, it might have been possible to reduce the size of this group.

Table 2.—*Cytological Diagnosis of 266 Cases of Bronchogenic Carcinoma*

Type of Tumor	Patients No.	Positive Diagnosis No.	Positive Diagnosis %
Epidermoid	113	94	83
Anaplastic	79	50	63
Adenocarcinoma	12*	6	50
Undetermined	43	38	88
Clinical	12	11	92
Alveolar	4	2	50
Fibrosarcoma	1	1	100
Mesothelioma	1	1	100
Carcinoma in situ	1	0	0
Total	266	203	

* In 2 cases the adenocarcinoma did not invade a bronchus.

Results of the cytological examinations were false-positive in only 0.8% of cases, but an additional 8.1% were falsely suspicious. Of the 97 patients with sputum specimens classed as 3 or suspicious, 44.2% were eventually proved to have pulmonary cancer, and the remaining patients were considered to be free of cancer according to the diagnosis at discharge. This is in essential agreement with other studies, which indicate about a 50% accuracy of a class-3 cytological report. False-positive results of examinations are a matter of concern in any cytology laboratory, and the source and meaning of the abnormal cells causing them remains obscure. In some cases, cancer may yet be proved, but these results emphasize the necessity of regarding cytological findings as adjuncts to other findings and of never considering this examination as diagnostic.

Table 3.—*Pulmonary Tumors Missed by Cytological Examination*

Type of Carcinoma*	Patients No.	Patients %
Epidermoid	19	30.2
Anaplastic	29	46.0
Undetermined	5	7.9

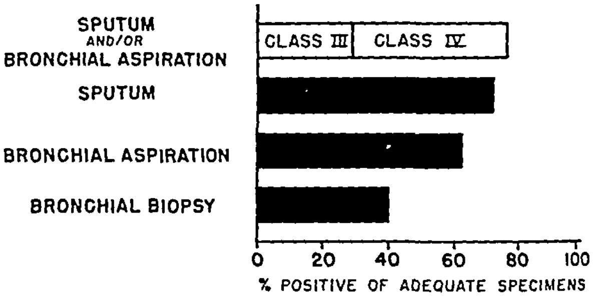
Alveolar	2	3.2
Carcinoma in situ	1	1.6
Clinical	1	1.6
Total	63	100.0

* In 2 cases the tumor did not invade a bronchus.

Table 4.—*Comparison of False-Positive Cytological Reports of Examinations of Specimens of Sputum and Bronchial Aspirate in 107 Cases*

Findings	Sputum	Bronchial Washing
Class 3	91	18
Class 4	8	3
Negative	4	34
Total	103	55
Examination not done	4	49
Inadequate	0	3

A comparison of the results of study of bronchial aspirates and sputum specimens in 203 cases of bronchogenic carcinoma reveals that sputum specimens are slightly more accurate than bronchial aspirates. In 172 cases adequate sputum specimens were obtained, and in 160 cases (93%) the results were positive. In 129 of these same cases adequate bronchial aspirates were obtained, and in the results of examinations (79.8%) were positive. Bronchial biopsy specimens were positive in 65 cases, or only 32%. Of 203 patients with pulmonary cancer, 61 had positive sputum specimens and positive bronchial washings, 25 had positive sputum specimens and negative bronchial washings, and 11 had negative sputum specimens and positive bronchial washings. In the remaining 106 cases either bronchial aspirates or sputum specimens were examined alone. There is little doubt that sputum examination can be of equal value with examination of bronchial aspirates in the detection or screening of cases for lung cancer. However, table 4 illustrates that false-positive reports are more frequent in sputum examinations than in the examination of bronchial aspirates. A class-3 report on a sputum smear must be carefully evaluated as atypical cells from the nasopharynx are more apt to be present in a sputum smear than in a smear of the bronchial aspirate.



Graph comparing the accuracy of examinations of specimens of sputum, bronchial aspiration, and bronchial biopsy in the detection of bronchogenic carcinoma.

In the diagnosis of 266 cases of pulmonary cancer the examination of sputum was slightly more accurate than the examination of bronchial aspirates, and the combination gave the highest percentage of accuracy (see figure). Since sputum is easily obtained with little expense and discomfort to the patient, it is felt that all patients with sputum should have this test available to them.

Comment

Cough and expectoration are commonly present in adults as a result of chronic irritation due to smoking, chronic bronchitis, or an acute pulmonary infection. The routine examination of the sputum of adults for tumor cells can be an effective method of suspecting bronchogenic carcinoma and may well arouse the suspicion of the disease while a cure is still possible. The data presented in this and other studies indicate that the results of such examinations of sputum are reasonably accurate. In this study they were slightly more accurate than the study of bronchial aspirates, which are appreciably more difficult to obtain. A cytological report of positive or suspiciously positive sputum should never be considered as establishing a diagnosis of cancer, but it can and should indicate the need for further study of a patient with bronchoscopy, laminagraphy, fluoroscopy, and other specialized radiologic techniques in an attempt to locate pulmonary cancer

Summary

In 1,203 patients a total of 3,102 specimens of sputum and bronchial aspirates were examined cytologically for presence of cancer cells In this series, 266 patients were ultimately believed to have bronchogenic cancer, and in all but 12 the diagnosis was established by histological examination Of 266 patients with bronchogenic cancer 76 3% had suspicious or positive results of cytological examinations for malignant cells in sputum or bronchial aspirates It was possible to establish a diagnosis somewhat more accurately with use of sputum specimens than with use of bronchial aspirates It is strongly urged that all patients with sputum have cytological examinations of secretions in an effort to make an earlier diagnosis of bronchogenic cancer

This study was supported by a grant from the New York State Division of the American Cancer Society and by a cancer teaching grant from the U S Public Health Service

Miss Helen Boris and Mrs Alice Koethen gave technical assistance in this study

COUNCIL ON DRUGS

Formerly the Council on Pharmacy and Chemistry

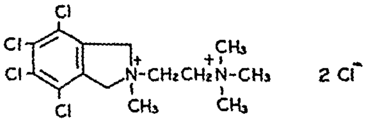
Monographs and supplemental statements on drugs described here and in subsequent editions of New and Nonofficial Drugs are based on the evaluation of available scientific data and reports of investigations Applicable commercial names for preparations of evaluated drugs are listed at the end of monographs and parenthetically in the text of supplemental statements, additional commercial names of which the Council is informed will be included with subsequently published supplemental statements and annual editions of New and Nonofficial Drugs

H D Kautz, M D, *Secretary*

NEW AND NONOFFICIAL DRUGS

Formerly New and Nonofficial Remedies

Chlorisondamine Chloride—4,5,6,7-Tetrachloro-2-(2-dimethylaminoethyl)isoindoline dimethylchloride—The structural formula of chlorisondamine chloride may be represented as follows



Actions and Uses—Chlorisondamine chloride, a quaternary ammonium compound, is a ganglionic blocking agent with pharmacological actions similar to those of other agents in this category It is more potent than the hexamethonium salts and pentolinium tartrate, but less so than mecamylamine hydrochloride The drug produces a somewhat longer duration of action than does hexamethonium, ganglionic blockade and resultant hypotensive effects generally persist for 8 to 12 hours after a single therapeutic dose Absorption from the gastrointestinal tract is rapid but, as with the older ganglionic blocking agents, is unpredictable and erratic Hence, precise control of hypertension is more easily achieved with parenteral injection than by oral administration

Chlorisondamine chloride is used for the management of the more severe forms of hypertension, including the malignant phase of this disease When used in adequate amounts, the drug effectively lowers diastolic and systolic blood pressure in most patients Because of the potency and potential toxicity of this agent, ganglionic blockade should not be initiated with it unless the patient can be kept under close supervision It should never be used for the treatment of mild, labile hypertension

Side-effects associated with chlorisondamine chloride are the same as with other ganglionic blocking agents Blurring of vision, dryness of the mouth, and postural hypotension occur frequently after therapeutically effective doses, urinary retention, especially in older patients with prostatic hypertrophy, is another potential complication Constipation, which can proceed to paralytic ileus, also must be guarded against The drug is contraindicated after cerebral vascular accidents or myocardial infarction and in patients with renal or coronary insufficiency, obstructions at the neck of the bladder, or pyloric stenosis

Dosage—Chlorisondamine chloride is administered orally, subcutaneously, or intramuscularly In general, parenteral injection should be reserved for the initiation of therapy in hospitalized patients with acute hypertensive crises Oral administration may be used for maintenance therapy in these patients and also for ambulatory patients with less acute forms of hypertension Dosage by either route must be highly individualized initial dosage should be low and increased by small increments until the desired therapeutic effect is obtained.

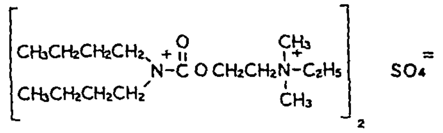
For parenteral injection by either the subcutaneous or intramuscular routes, the initial dose should not exceed 2.5 mg. Depending on response, this may then be increased by increments of 1 mg at intervals no more frequent than every eight hours. The effective single dosage by the parenteral routes will usually range between 1 and 10 mg. Once hypertension has been stabilized, maintenance by the oral route may be substituted, using approximately twenty times the injectable dose.

For oral therapy in ambulatory patients, the initial dose is 10 mg taken in the evening. The next day, dosage is increased to 10 mg in the morning and again in the evening. On the third day, 10 mg is administered in the morning and 20 to 25 mg in the evening. Dosage is increased to 20 to 25 mg in the morning and again in the evening on the fourth day. The morning dose for the fifth day is 20 to 25 mg followed by 35 to 50 mg in the evening. Thereafter, dosage is increased in the stepwise fashion indicated previously, by 10 to 25 mg increments, up to approximately 200 mg per day, depending on response.

Applicable commercial name Ecolid Chloride

Ciba Pharmaceutical Products Inc cooperated by furnishing scientific data to aid in the evaluation of chlorisondamine chloride

Dibutoline Sulfate.—Bis[dibutylcarbamate of ethyl-(2-hydroxyethyl)dimethylammonium] sulfate.—The structural formula of dibutoline sulfate may be represented as follows:



$$\left[(CH_3CH_2CH_2CH_2)_2N-\overset{O}{\overset{\|}{C}}\,O\,CH_2CH_2\underset{CH_3}{\overset{CH_3}{\overset{+}{N}}}-C_2H_5\right]_2 SO_4^{=}$$

Actions and Uses.—Dibutoline sulfate, a synthetic choline ester, is related in chemical structure to acetylcholine; however, it depresses instead of stimulates the parasympathetic nervous system. The drug exerts a direct spasmolytic effect on smooth muscle and, by interfering with the liberation and/or accumulation of acetylcholine, blocks physiological functions dependent on cholinergic transmission. Thus, the principal pharmacological actions as well as the side-effects of this drug are chiefly atropine-like in nature. Dibutoline sulfate differs from atropine sulfate mainly in exerting a more rapid and intense but shorter duration of action. Unlike atropine and some of the other synthetic anticholinergic drugs, dibutoline is ineffective by the oral route and requires parenteral injection.

Since it diminishes gastric secretion and antagonizes hypermotility, dibutoline sulfate is useful for the adjunctive management of peptic ulcer. The drug may likewise be expected to produce prompt relief of pain and discomfort associated with certain other spastic conditions of the gastrointestinal tract such as functional pylorospasm, acute gastroenteritis, and the irritable colon syndrome.

Dibutoline sulfate has also been used for the treatment of certain spastic disorders of the biliary and genitourinary tracts. These include functional spasm of the sphincter of Oddi, biliary colic arising from cholelithiasis, urinary bladder spasm after cystoscopy or transurethral prostatic resection, and premenstrual cramps. In view of the close similarity of this drug to atropine, which has not proved to be of particular value in these conditions, the usefulness of dibutoline in the foregoing spastic disorders is somewhat questionable.

The toxicity of dibutoline sulfate is low, and its margin of safety is wide. The chief side-effects are transient xerostomia and moderate diminution of ocular accommodation. No significant tachycardia or alterations in blood pressure have been observed. As with all agents of this class, dibutoline sulfate is contraindicated in patients with glaucoma, prostatic hypertrophy or other obstructions at the neck of the bladder, pyloric or duodenal obstruction, and stenosing peptic ulcer.

Dosage.—Dibutoline sulfate is administered only by subcutaneous or intramuscular injection. Dosage must be individualized according to the response of the patient and the appearance of side-effects. The usual dose by either parenteral route is 25 mg. This may be repeated three or four times daily as indicated and tolerated.

Applicable commercial name Dibuline Sulfate

Merck Sharp & Dohme Research Laboratories Division of Merck & Co, Inc, cooperated by furnishing scientific data to aid in the evaluation of dibutoline sulfate

Fumagillin.—An antibiotic elaborated by strains of Aspergillus fumigatus.—The chemical structure of fumagillin has not been determined.

Actions and Uses.—Fumagillin, an antibiotic used clinically as an amebicide, is highly active in vitro and in vivo against Entamoeba histolytica and some nonpathogenic strains of ameba. The drug has no effect on fungi or bacteria; hence, oral therapy is not complicated by overgrowth of monilia or other alterations in the flora of the gastrointestinal tract. In contrast to certain other antibiotics used in amebiasis, fumagillin exerts a direct lethal effect on E. histolytica rather than suppresses bacteria essential to its proliferation. The excretion and metabolic fate of fumagillin are imperfectly known. However, the fact that systemic side-effects do occur indicates at least partial absorption of this antibiotic.

Fumagillin may be used for the treatment of intestinal amebiasis; it has no effect in the extraintestinal form of the disease. On the basis of current evidence, it is considered about as effective as oxytetracycline or older drugs such as the iodinated compounds and the arsenicals. The cure rates reported after a course of therapy with fumagillin vary from 55 to 95%. It is believed that the latter figure could be approached more frequently if adequate precautions against reinfections were observed. Therapy cannot be considered successful unless at least two successive stool examinations are negative for motile ameba (trophozoites) and/or cysts. When extraintestinal amebiasis is present or suspected, fumagillin should not be used Therapy in such cases should be restricted to agents known to suppress this form of the disease

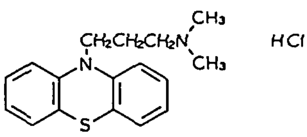
Side effects are frequently encountered during therapy with fumagillin, especially at high dosage levels Although they are sometimes sufficiently troublesome to require discontinuation of therapy, they are seldom serious and are usually reversible Among these side-effects are abdominal cramping and an epigastric burning sensation, diarrhea, anorexia, nausea and vomiting, headache, vertigo, and a vesicular type of skin eruption, which may be followed by mild desquamation Fumagillin has also been implicated as a possible causative agent in a few cases of neutropenia Until the possible adverse effects of this antibiotic on the hematopoietic system can be more thoroughly elucidated, peripheral blood cell counts are a wise precaution during prolonged therapy

Dosage—Fumagillin is administered orally in doses of 40 mg a day in four divided doses over a period of 10 to 14 days In more resistant cases, maximum daily doses up to 60 mg may be tried, but this dosage level may be associated with increased toxicity For children and severely debilitated patients, dosage should be calculated on the basis of age and weight

Applicable commercial name Fumidil

Abbott Laboratories cooperated by furnishing scientific data to aid in the evaluation of fumagillin

Promazine Hydrochloride—10-(3-Dimethylaminopropyl)phenothiazine hydrochloride—The structural formula of promazine hydrochloride may be represented as follows



Actions and Uses—Promazine hydrochloride is identical in chemical structure to chlorpromazine hydrochloride, except that it lacks the chlorine atom on the ring structure The general pharmacological properties of these two phenothiazine derivatives are likewise very similar, the chief difference being a lower acute toxicity with promazine after oral and parenteral administration to experimental animals

Promazine hydrochloride is used in the same manner as chlorpromazine hydrochloride for the treatment of acute neuropsychiatric agitation It effectively allays the apprehension and anxiety that accompany various types of acute psychoses, it is also reported useful in the management of such alcohol-induced syndromes as delirium tremens, acute hallucinosis, and tremulousness On the basis of currently available evidence, promazine appears to be essentially equivalent to chlorpromazine as a neuropsychiatric agent It has not been studied for a sufficiently long period to warrant its routine use in chronic mental disturbances, nor has it been evaluated as an antiemetic agent

Preliminary reports indicate that some of the more serious toxic manifestations of chlorpromazine have not yet been encountered with promazine In view of their close structural relationship, however, it is possible that any of the untoward reactions attributed to chlorpromazine could occur after promazine therapy Jaundice and hypoplastic anemia have not been reported, but transient leukopenia, agranulocytosis, and convulsive seizures have been observed in a few patients These side-reactions, as well as less serious side-effects such as orthostatic hypotension and undesirable drowsiness, occur with about the same frequency as with chlorpromazine Thus it is impossible to assess with finality the ultimate toxicity of promazine as compared with chlorpromazine Until more clinical experience has accumulated, both should be administered with the same degree of caution (See the monograph on chlorpromazine hydrochloride in New and Nonofficial Remedies)

Dosage—Promazine hydrochloride is administered orally, intramuscularly, or intravenously Dosage is *highly individualized depending on the severity of* symptoms and the degree of response Whenever possible, the oral route should be employed, since parenteral administration enhances the possibility of orthostatic hypotension As a general guide, total daily doses ranging from 25 to 300 mg may be employed If the response is not satisfactory, doses up to a maximum of 1 Gm a day may be tried In all cases, the smallest effective dose should be used

Applicable commercial name Sparine Hydrochloride

Wyeth Laboratories Division of American Home Products Corporation cooperated by furnishing scientific data to aid in the evaluation of promazine hydrochloride

Mumps Orchitis—There is little to be gained from the routine use of cortisone acetate in treatment of the minimally involved testicle Control patients and treated patients revealed no difference in their response to therapy, either subjectively or objectively, and all were clinically well within 3 to 4 days It does seem justified, however, to treat patients who have moderately severe or severe orchitis with this hormone if certain factors are kept in mind As in many other conditions where cortisone acetate is of benefit, the principal good derived is due to the antiphlogistic action of the hormone as the drug exerts no direct action on the causative organism Therefore, adequate dosage is important and, in particular, a sufficiently prolonged course is necessary to cover the ordinary period of the inflammatory process in the testicle if a clinical relapse is to be avoided There is no evidence to show that the natural course of orchitis is shortened by the use of cortisone acetate With these limitations and factors in mind, moderate to excellent symptomatic relief for the patient is to be expected—Lieut Col E S Stenberg Jr and Col W C Berry, M C, U S Army, The Use of Cortisone in the Treatment of Mumps Orchitis, *United States Armed Forces Medical Journal,* October, 1956

COUNCIL ON FOODS AND NUTRITION

The following paper was presented at the symposium, 'The Relation of Proteins and Amino Acids to Human Nutrition,' in Los Angeles, May 21, 1956 This symposium was sponsored by the Council on Foods and Nutrition, with the cooperation of the Los Angeles County Medical Society and the School of Medicine, University of California at Los Angeles This report is the first of the series After publication of the sixth and final report, this series will be available in monograph form

PHILIP L WHITE, Sc D, *Secretary*

ROLE OF THE DIGESTIVE TRACT IN THE UTILIZATION OF PROTEIN AND AMINO ACIDS

E S Nasset, Ph D, Rochester, N Y

Report to the Council

The modern renaissance in the study of the chemistry and physiology of the proteins is vigorous, universal, and greatly significant for health Mulder the Dutch chemist, was profoundly prophetic in 1839 when he coined the term 'protein to denote the primary importance of these compounds for the animal organism [1] The very fact that this symposium is being held more than a century later is additional evidence of the continuing and intense interest in the proteins and their special and increasing importance in nutrition

In the United States World War II evoked considerable interest in nutrition as it applied to the feeding of servicemen and industrial workers In Europe, whole nations were placed on restricted rations, and much scientific planning was required to devise adequate diets with only a limited quantity and variety of foods Probably the most successful of the rationing schemes was the one used in the United Kingdom On the continent as the war progressed, it became necessary to plan emergency feeding of half-starved civil populations as were found in The Netherlands, as well as the soldiers who, as prisoners of war, had been neglected by the enemy The most significant facts to come out of these experiences were that vitamin deficiencies occurred rarely and that the prevalent protein deficiencies could be remedied by the administration of large amounts of protein in the form of an aqueous suspension of dried milk and dried eggs Many experts assumed that the semistarved person would be unable to digest protein and would require a protein hydrolysate to initiate his realimentation The sheer size of the task of rehabilitation prevented the widespread use of hydrolysates, and from necessity, the discovery was made that even the severely undernourished and emaciated person could tolerate large quantities of protein [2]

Another important factor in the immediate postwar activity in the study of protein metabolism was the commercial availability of the crystalline essential amino acids Prior to this time, much of the research had been devoted to a determination of the amino acid requirements for growth This was true, in part, because the investigator frequently was obliged to isolate some of the amino acids from natural sources He was not keen, therefore, to give them in large amounts, hence he often confined his feeding experiments to the small, rapidly growing animals

Digestion and Absorption of Proteins

In 1947 a project was begun in the University of Rochester laboratories to establish the essential amino acid requirements for the maintenance of nitrogen equilibrium in the adult male rat In order to keep the intake of calories and nitrogen constant, the animals were fed a synthetic diet by means of a stomach tube twice daily Each essential amino acid in turn was reduced in amount until it became the limiting factor in the utilization of the total nitrogen of the diet From the data on nitrogen balance obtained, it was possible to compute individually the essential amino acid requirements under specified conditions [3] With this information in hand, a new amino acid mixture was designed to provide the essential amino acids in the proportions indicated by the individual determinations Feeding trials with this new mixture showed it to be inferior to isonitrogenous quantities of either whole egg protein or a mixture of amino acids that simulated whole egg in essential amino acid composition [3A] This disappointing result was an important stimulus for the work on protein digestion that forms the basis for the present paper

Intact Protein Absorption—The digestion and absorption of proteins have been investigated over a long period of time Voit and Bauer [4] introduced egg albumin solutions into the loops of the jejunum in the cat and observed that 15 to 45% of the protein disappeared in one to four hours Heidenhain [5] discovered that 30 to 40 ml of homologous serum placed in an isolated loop of the jejunum of a dog disappeared in less than an hour Serum that was concentrated by removal of water was also completely absorbed In this connection, it is pertinent to point out that the juice secreted by the intestinal mucosa does not contain a proteinase, hence it is not likely that the serum proteins were hydrolyzed The family of peptidases secreted in the succus enteri

---

From the Department of Physiology, University of Rochester School of Medicine and Dentistry cus, first described as erepsin,[5] can act only upon peptide substrates and particularly upon those resulting from the action of gastric and pancreatic proteinases. The work of Murlin and co-workers[6] demonstrated hypoglycemia under some conditions when insulin was placed in a Thiry-Vella loop of the small intestine. Since the characteristic hypoglycemic action of insulin depends upon its molecular integrity, the results of Murlin and co-workers clearly show that insulin can pass the mucosal barrier as an intact protein. Recently Gruskay and Cooke[7] demonstrated that infants normally absorb small amounts of unchanged egg albumin and that, during recovery from diarrhea, the absorption may be increased five-fold and become an important factor in sensitizing the infant to egg albumin. The evidence is conclusive that, under special conditions, the intestinal mucosa absorbs protein molecules unchanged.

Amino Acid Absorption.—A preponderance of evidence supports the view that food proteins normally are completely hydrolyzed to their constituent amino acids prior to absorption. The ingenious experiments of Abel and associates[8] with "vividiffusion" showed without doubt that ingestion of protein resulted in a greatly increased concentration of diffusible amino acids in the circulating blood. They described a nonprotein fraction thought to be composed of peptides but offered no evidence that this fraction had its origin in the intestinal lumen. Dent and Schilling[9] attempted unsuccessfully to demonstrate a rise in peptides of portal blood after feeding casein, beef muscle, and human serum albumin to dogs. The total amino acid concentration rose in portal blood as a result of feeding these proteins, but the relative concentrations of the various amino acids did not reflect differences in the nature of the ingested protein. In gastrectomized dogs, the results of feeding homologous protein in the form of whole plasma were quite different in that the concentration of amino acids in the portal blood failed to rise. Postmortem examination of one of the animals showed that the plasma administered by means of a stomach tube had disappeared completely from the digestive tract. Dent and Schilling suggested that homologous plasma protein may be absorbed intact, thus lending support to the earlier work of Voit and Bauer and Heidenhain.

The work of Wilson and Lewis[10] demonstrated that various individual free amino acids tested singly disappeared from the lumen of the intestine at different rates. D-Alanine was absorbed to the extent of 77 mg. per 100 Gm. of body weight per hour over a three-hour period; L-leucine was absorbed at about 56% of this rate. The dosages of amino acid given to the rats used in this work were rather large; they varied from approximately 200 to 450 mg. per 100 Gm. of body weight, which corresponds to a dosage of 140 to 315 Gm. for a man who weighs 70 kg. (154 lb.). According to Doty and Eaton,[11] histidine was absorbed at a rate of 57 mg. per 100 Gm. of body weight per hour in the rat over a two-hour period, and lysine was absorbed at 37% of this rate. The dosages of histidine and lysine were also rather high.

Hober and Hober[12] concluded that amino acids are transported across the intestinal mucosa by a special mechanism. The rates of amino acid absorption were compared with those of nonphysiological but inert organic compounds. In all experiments, the amino acids were absorbed much faster than the comparison compounds despite the fact that the effective molecular volumes of the comparison compounds were smaller than those of the amino acids. These investigators also reported differences in absorption among several amino acids; for example, glycine was always absorbed faster than either valine or alanine.

The work of Gibson and Wiseman[13] indicates another interesting aspect of amino acid absorption. These investigators introduced solutions of single racemic amino acids and found that the L-isomer was absorbed 1.6 to 6.0 times faster than the D-isomer. Apparently the natural isomer can compete to better advantage for a place in the transport system. Their results also indicate some differences in rates of absorption among the various L-isomers.

The absorption of a particular amino acid may be decidedly altered in the presence of one or more other amino acids. Pinsky and Geiger[14] reported that the absorption of L-histidine in the rat is greatly reduced in the presence of L-tryptophan. The absorption of L-tryptophan, however, did not appear to be affected by the presence of histidine. The absorption of neither one of these seemed to be significantly altered by the presence of either DL-phenylalanine or L-arginine. This experiment demonstrates very clearly that the data obtained for the absorption of individual amino acids may not be applicable to mixtures, even though they contain no more than two or three different amino acids. When the intestine contains all of the amino acids normally found in food proteins, data for the absorption of single amino acids cannot be used to predict the behavior of the mechanism for absorbing amino acids.

On the basis of this brief review, the following tentative conclusions are made: 1. Certain proteins such as homologous plasma proteins, egg albumin, and insulin may be absorbed in varying amounts without undergoing the usual enzymatic hydrolysis in the digestive tract. 2. The naturally occurring isomers of the common amino acids are preferentially more rapidly absorbed than the D-isomers, which fact strongly suggests active transport of the L-isomers across cell membranes. 3. The rates of absorption observed for single amino acids are not applicable to complex mixtures. 4. The amino acid transport system has a limited capacity, and the amino acids in a mixture compete for places in this system.

Protein Metabolism

Do any or all of these facts help to explain any of the puzzling phenomena in protein metabolism? The differences in rates of absorption, if real, could be interpreted to mean that differences in biological values of proteins might be caused by unequal supplies of the essential amino acids at the sites of synthesis. The work of Elman[15] on intravenous feeding demonstrated that all of the essential amino acids had to be injected simultaneously in order to attain the maximum favorable effect upon nitrogen balance This concept was confirmed by Geiger,[16] who showed that tryptophan supplied daily to rats 12 hours after they had consumed a diet deficient in tryptophan was ineffective as a supplement to the deficient amino acid mixture

The results of Elman and Geiger as well as the failure to achieve the 'ideal' amino acid mixture led me and my co-workers to look elsewhere for more information Dogs were fed various test meals and were killed for chemical examination of the contents of their digestive tracts These analyses included the determination of 16 microbiologically available amino acids[17] An egg albumin test meal was used as representative of a complete protein of high biological value, and zein served as the test meal representative of an incomplete protein of low biological value A mixture of sucrose and lard served as the nonprotein control test meal Approximately 1½ hours after being fed the test meal, the animal was killed Ligatures were quickly placed at the cardia, pylorus, ligament of Treitz, and at the upper quarter, midpoint, and terminus of the remainder of the small intestine These ligatures delimit the stomach, duodenum, jejunum, upper ileum, and lower ileum In two dogs all pancreatic ducts had been ligated several weeks prior to the feeding experiment

The results (table 1) indicate that the total nitrogen recovered from various parts of the small intestine remained constant in the normal animal regardless of the protein in the test meal The feeding of the nonprotein meal resulted in progressively greater amounts of nitrogen recovered from the segments distal to the pylorus, but at most the quantity was no more than one-third to one-half of the amount recovered after feeding protein The amount of nitrogen ingested does not affect appreciably the amount of nitrogen recovered from the small intestine Excess ingested protein is retained in the stomach and released gradually into the duodenum The rate of emptying of the stomach is governed by reflex an hormonal mechanisms rather than by the quantity o food ingested

Table 2 is an abbreviated summary of the amin acid analyses The results are expressed as moles o amino acid per mole of threonine, which was selecte as a basis of comparison because it seems to be presen in most proteins and is usually neither the most no the least abundant of the essential amino acids O this basis, the ingested proteins, egg albumin and zei display marked differences A comparison of the mol ratios of isoleucine, leucine lysine, tryptophan, an glutamic acid illustrates this point At first glance, i would seem that such differences in compositio would betray the presence of either of these protein in any segment of the digestive tract Inspection o the results of amino acid analysis of gastric content reveals that this does hold true, with certain reservations In the jejunum, however, the distinguishin characteristics have been lost, and without a labe it would be difficult to identify the test meal associate with either column of table 2 What is perhaps mor astonishing is the fact that a nonprotein test mea results in a jejunal amino acid mixture that ca scarcely be distinguished from those derived from protein test meals The ratios for the duodenum li between those of the stomach and jejunum, where those for the ileum duplicate essentially those for th jejunum It is difficult to escape the conclusion tha the ingestion of a meal, whether or not it contains an protein, results in the transfer of appreciable quantitie of nitrogenous material into the lumen of the smal intestine What can be the nature of this 'endogenous nitrogen? At this point it is well to recall that the hydrolytic enzymes are themselves proteins that th digestive juices also contain mucoproteins, and tha the intestinal mucosa is continually being desquamated Possibly these and other sources also ma provide enough endogenous protein to dilute the amino acid mixture in the intestine sufficiently t obscure any amino acid peculiarity characteristic o food protein

How does a mixture of digestive enzymes compare in amino acid composition with some amino acid mixtures that have been used in nitrogen balance experiments? Table 4 shows such a comparison, and it is easy to see that the resemblance is not close Table 5 shows the result of mixing equal parts of the same mixture of enzyme proteins with either egg albumin or zein Such a mixing tends to make the two combinations resemble each other In table 6 these calculated results are compared with the actual results found on analysis of jejunal contents With a few exceptions, the agreement between "found and calculated' values is valid enough to lend support to the idea that, during the process of digestion, a great deal of endogenous protein is transferred into the lumen, is there hydrolyzed, and is recovered as amino acids mixed with the amino acids of the ingested protein This may be regarded as a homeostatic device that, within limits, assures the liver and other sites of protein synthesis a mixture of amino acids normally subject to a minimum of qualitative variation

Rate of Absorption of Amino Acids—Is there any evidence of great differences in the rate of absorption of the individual amino acids from intestinal contents? From experiments on the absorption of the individual amino acids, it may be concluded that such differences do occur The following relative rates of absorption may be computed from the data of Gibson and Wiseman[13] histidine, 6, valine, 3 5, phenylalanine, 3, methionine, 2 5, and lysine, 1 The data of Nasset and associates[17] are rearranged in table 7 to test whether these amino acids in a mixture that contains them all do, in fact, leave the lumen at such widely different rates It seems reasonable to suppose that if histidine, or any other single amino acid, were absorbed very rapidly, the contents should gradually become impoverished in this amino acid as they proceeded toward the ileum Conversely, the more slowly absorbed amino acids should accumulate, relative to the quantity of histidine, as the contents approached the ileum The data in table 7 do not support this idea Disregarding the stomach, where no absorption occurs, the relative concentrations of the five amino acids remain quite stable The last four amino acids are slightly concentrated with respect to histidine, but the relative changes are all of the same order and fail to reflect any differences among the four The relative concentrations of these five essential amino acids tend to remain fairly constant throughout the small intestine, and there is no reason to believe that the others would behave differently If this were not true, the effect in the blood stream could be comparable to administering a few amino acids at one time and a few more somewhat later This is the type of amino acid influx that has been shown by Elman[15] and by Geiger[16] to be inefficient for protein synthesis

Gastrointestinal Factors—In the figure are listed some of the gastrointestinal factors that may play a role in the utilization of protein, the basic physiology of the digestive tract enters prominently into this problem To a large extent, nutrition workers have acquired their knowledge of digestive processes from results of studies of isolated enzyme systems in vitro The classic idea of optimum pH for such enzyme systems leads to the conclusion that the digestive apparatus must be operating at low efficiency because the pH in the stomach (2-6) is often too high for optimum' pepsin activity, and the pH of the small intestine (4 5-6 5) is too low for 'optimum" activity of the pancreatic and intestinal enzymes Despite this paradox, the digestive enzyme mechanisms operate at much greater speeds in vivo than are realized in laboratory experiments in vitro

† Assuming equal quantities of food protein and enzyme protein composed of equal quantities of pepsin amylase trypsinogen chymotrypsinogen and carboxypeptidase

The emptying of the stomach is obviously a very important factor in keeping the intestine supplied with just the right amount of material The dual nervous and hormonal control, represented by the enterogastric reflex and enterogastrone, respectively, is very well coordinated to prevent overloading of the duodenum

The sources of endogenous protein are the digestive secretions and the mucosal cells that are constantly sloughed Information on the quantity and composition of the various secretions is rather limited, but it is estimated that 50 to 100 Gm of endogenous protein material is transferred into the digestive tract of a human adult every day Of this not more than 10 to 15 Gm is lost in the stool The remainder is recovered and represents a large and extremely mobile protein reserve In a sense, therefore, all human beings are cannibals, and the usual concept of vegetarianism is a myth

† Relative concentration

This work is reported with full recognition of the basic and well-founded concepts of the essentiality of certain amino acids and the biological value of dietary proteins It is still considered impossible for the mammal either to synthesize essential amino acids or to avoid the unfavorable consequences of continued consumption of an incomplete protein The homeostatic mechanism here described probably serves to even out temporary irregularities in the dietary supply of amino acids and to prevent gross changes in the amino acid pattern of the portal blood This pattern in cells and extracellular fluid is easily unbalanced by administration of single amino acids,[18] which represents a very real hazard in the fortification of foods with amino acids

Summary

The ingestion of protein stimulates the digestive tract to secrete endogenous protein, which becomes mixed with the food protein to provide an amino acid mixture for absorption that remains relatively constant in composition Proteins of widely different amino acid composition and even nonprotein foods give rise to amino-acid mixtures in the small intestine that are similar The result of this mixing of amino acids in the lumen of the intestine may be to regulate rather closely the relative concentrations of the amino acids available for absorption

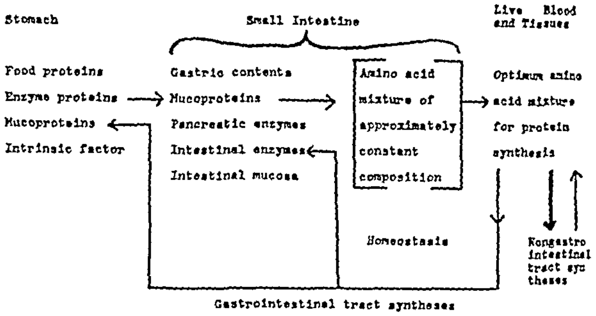

Diagram showing gastrointestinal role in utilization of protein

Nothing said here is intended to deny or to refute such basically sound nutritional concepts as the need for dietary essential amino acids or the differences in the biological values of dietary proteins

COUNCIL ON MENTAL HEALTH

This is the last in a series of four articles prepared by members of the Committee on Alcoholism of the A M A Council on Mental Health The other articles appeared in THE JOURNAL *on Dec 29, 1956, Feb 16, 1957, and March 2, 1957*

RICHARD J PLUNKETT, M D, *Secretary*

SOCIAL SETTINGS CONDUCIVE TO ALCOHOLISM

A SOCIOLOGICAL APPROACH TO A MEDICAL PROBLEM

Selden D Bacon, Ph D, New Haven, Conn

The sociological approach to alcoholism could be applied to such matters as diagnosis, epidemiology, rehabilitation, prevention, medical education, and the impact of institutional care In all these instances the attitudes and behaviors and the social structuring of human beings form an essential element in that which occurs Whether it be attitudes that prevent an alcoholic from coming into contact with a therapist, a difference between therapist and patient in relation to learned aspirations, inhibitions, and beliefs in what is "natural and good," or a specific set of cultural notions about drinking, the so-called sociological aspects can be not only relevant but even crucial for the emergence of different symptoms, different patient-physician relationships, different therapeutic results Naturally, this in no way detracts from the significance of other approaches During this period in our culture it does seem, however, that the sociological approach is more immediately germane to alcoholism than it might be to pneumonia, cataracts, or a broken leg

This presentation will be limited to illustrating the sociological approach, and consideration will be restricted to one application in the area of etiology The purpose is not to "explain alcoholism or present clinical techniques for therapy, or even to describe the condition sociologically It is to present one example of the sorts of data, the sorts of measurement, and the sorts of conclusion, that can stem from this social science approach and that may prove useful to the medical practitioner

Described sociologically, alcoholism is viewed as a behavioral phenomenon It is in one sense more effectively defined by sociology at this time than by other disciplines for the simple reason that it forms a unique syndrome, one not easily confused with any other, e g, unemployed, atheists, bachelors, Kansans, collegians, drug addicts It is largely the current lack of such uniqueness that has made psychological and physiological descriptions rather murky

As a sociological phenomenon, alcoholism will be described in terms of specified behaviors of the alcoholic and their degree of differentiation from comparable behaviors of others, these behaviors may be subdivided into such classifications as actions, attitudes, and group membership, the behaviors being patterned and repetitive The condition will also be described in terms of the patterned and repetitive behaviors of significant others responding to the alcoholic and his behaviors These also may be subclassified as above

---

Professor of Sociology, Yale University, Director, Yale Center of Alcohol Studies, and Chairman, Connecticut Commission on Alcoholism

Whether one is studying the behaviors of the alcoholic or of those responding to him, two perspectives are of essential importance. One of these is sociocultural orientation: whether the condition or the afflicted individual is considered, it is always in terms of the specific cultural group. Therefore, in contrast to the usual medical orientation, the sociological analysis will never, except in terms of high-level abstraction, relate to alcoholism as a condition of Homo sapiens but always in terms of a specified sociocultural context, e. g., Greek alcoholism, upper-class Canadian alcoholism in those of English background, Mexican-Indian alcoholism.

The second perspective is that of time. This refers not only to time periods for a culture but also to time periods in the individual life history. For example, the behavioral deviations of an alcoholic must be viewed against his sociological development. If three individuals manifested approximately the same alcoholic behavioral deviations at age 45, it would not necessarily mean they were of the same subtypes of alcoholism from a sociological viewpoint (although from a legal or physiological viewpoint they might be extremely similar). One of the three individuals might never have taken on effectively the values, inhibitions, and aspirations of the culture; he might be called "undersocialized," and many so-called Skid Row types might be so described. A second might have taken on the culture in an unbalanced, even twisted fashion with excessive anxieties and guilts at one point and with apparent minimal aspirations at another; perhaps many so-called neurotic alcoholics would be of this type, and they could in this terminology be called "dissocialized." Still a third might have been socialized in relatively average fashion for his social milieu, but he might have left the group so that the particular social learning was unlearned and other, differing values and practices learned; certain emigrés and perhaps some isolated occupational groups may suggest representatives of such a "desocialized" category. Despite the manifest behavioral (and perhaps also physiological, psychological, legal, and other) similarities of three such persons in the late stages of alcoholism, they would represent decidedly different categories from a sociological viewpoint.

Some Common Behavioral Symptoms

Very briefly to describe some of the typical signs of the present-day alcoholic among white, Protestant males of northern European cultural orientation living in urban areas of the northeastern quarter of the United States, the following list might be offered. In each instance the behaviors, attitudes, or memberships are deviations from an average of the individual's own particular stratum within this large and complex population. Very roughly, these signs approximate a progression from the earliest to the last stages of the condition.

1. Compared to other persons of his appropriate social group, the alcoholic consumes more alcohol and does so more frequently. 2. He hides this consuming. 3. He consumes at times much more rapidly, often gulping. 4. He experiences periods of temporary amnesia. 5. He exhibits excessive deviations in behavior while using alcohol. 6. After the first drink he shows a loss of rational control over further consumption. 7. He develops excessive, new, and socially unacceptable explanations about his use of alcohol. 8. He may often imbibe when alone. 9. He may imbibe to "start off" the day. 10. Directly related to his use of alcohol, he begins to lose friends, family relationships, jobs, etc. 11. He attempts new ways of using alcohol (e. g., only wine, only every other day, only with particular persons) or occasionally stops all use for specified periods. 12. He seeks outside help. 13. He manifests rather extraordinary fears and resentments. 14. He indulges in "benders," prolonged periods during which intoxication blots out all socially expected and prescribed activities and relationships. 15. He may manifest psychotic episodes and certain physical stigmas. 16. He may hit both psychological and sociological bottom, now making no attempts to behave or to make rationalizations about his behavior that would fit any acceptable norm.

Alcoholism Etiology—General Considerations

Psychological factors are generally felt to be the critical item in explaining the initiation of alcoholic drinking, the early repetitive deviant drinking behaviors such as those discussed above. Alcohol is an anesthetic or depressant, and its action is approximately the same on all human central nervous systems. It is usually described as reducing the speed and accuracy of perception, slowing down reaction time, and diminishing tensions, anxieties, and inhibitions. These functions, however, may have markedly different impact upon differing personalities. The person who is noticeably shy or overly repressed or who appears to struggle with too heavy a load of self-imposed guilt is felt to be psychologically susceptible to the development of alcoholism. Nor is it considered necessary for such characteristics to be particularly marked at the ages of 17 to 23 years, a common period in the United States for initiation of the custom of drinking. Such features might remain fairly well masked through young adulthood. With increasing pressures of social expectancy (as interpreted by the individual) of marriage, parenthood, occupational or professional progress, menopause, or persistent situations calling for behaviors, achievements, or status that the person cannot meet without increased and unmanageable anxieties, the susceptibility will become increasingly marked. Alcohol might be reacted to with extreme behavior at the very onset of drinking at ages under 20 years, or the person might indulge in a socially controlled fashion for several years before showing the drinking deviations characteristic of the alcoholic. In the latter case the deteriorating sociopsychological function of excessive intake of alcohol may appear etiologically of considerable importance for final emergence of alcoholism. On the other hand, in the noticeably neurotic person of 19 or 20 who with the onset of drinking begins to show deviant behaviors, the etiological significance of the alcohol is felt to be less important.

Basically, then, one set of questions about etiology concerns the factors lying behind the emergence of those personality sets characterized by what are called excessive feelings of anxiety, guilt, inadequacy, and he like It is generally agreed that these feelings are earned, as also are the more or less acceptable ways of handling them The social value systems from which he individual of necessity gains his interpretations of self and of ideal, the form of social structure hrough which these systems come to him, the sanctions that direct and reinforce his learning, and the eality situations through which he lives—all these clearly are essential parts of his learning However, hat these social factors determine the emergence of his or that particular anxiety or make socially acceptable adjustment impossible—this is a different matter entirely The unique individual experiences, environment, and learning processes can provide such an elaborate, even enormous range of individual developments that psychological factors are almost certainly of the same general order of significance as are he sociological ones Lying behind both of these may well be physiological differences that would tend to accentuate certain types of intensities of behavioral differences (whether socially acceptable or not) and hus be significant for so-called neuroses in one society and for more normal life patterns in another

On this very basic level, physiological, psychological, and sociological factors are probably all of as yet unknown degrees of importance However, as one moves to the next level, greater discrimination is possible Granted that the individual is suffering somewhat more than the average member of his group rom anxieties, tensions, guilts, and feelings of inadequacy and further granted that he is introduced to the drinking of alcohol beverages, why does he become an alcoholic? The question becomes highly pertinent when it is noted that many such suffering persons do use alcohol beverages and do not become alcoholics Certainly the use of alcohol by itself does not cause alcoholism, since it is observed that only a small percentage of users (well under 10%) ever become alcoholics The fact that many unhappy, neurotic, or maladjusted persons use alcohol beverages and do not become alcoholic suggests that a etiology more specific than the commonly ascribed (and vaguely defined) psychological anomaly or maladjustment must be sought

Variation in Drinking Culture and Incidence of Alcoholism—Four Groups as Examples

On the sociological side there have developed in very recent years some hypotheses about specific conditions that may be viewed in terms of social and cultural terrains that are more and less favorable for he emergence of alcoholism They may even be interpreted as causative from some points of view The sociological approach is based upon study of the manifest behaviors, attitudes, things, and group-membership patterns that form a constellation centering upon the customary use of alcohol beverages within a specified society Collections of this sort of data, when classified, allow descriptions of the prevalence of more or less deviation from norms There are many sorts of deviation from norms of the constellation of behaviors that may be called the drinking custom in our society, e g, false labeling, icing the wine, bootlegging, drinking by a participant prior to a contest of skills Here we are interested in the deviations related more directly to the behavioral syndrome labeled alcoholism

One sociological question would be "Does this syndrome appear more frequently with sociological constellations of one sort than with those of another sort? The answer would appear to be an undoubted affirmative It is not possible in a paper of this length to do more than sketch some generalizations relevant to such studies in terms of rather extreme examples

First Example—The first example concerns a current American group in which the social functions of drinking are strikingly clear drinking is to draw the family together, to cement the bonds of larger group membership, to activate the relationship between man and deity This is understood by the participants The rules and procedures of drinking are about as ritualized as those of a university football game or a church service

Violations of the rules, or violations of propriety while drinking, are quickly and severely sanctioned, and all sanctioning roles (father, neighbor, community leader, occupational leader, elders, etc) join uniformly in such negative sanctions The custom does not show much differentiation by subsocieties or subclassifications of the group, although men, adults, and wealthy persons tend to drink more frequently The custom is learned from infancy, it is instilled at the time that basic moral attitudes are learned and is taught by the prestigeful members of the group (parents, ministers, elders) The custom is closely entwined with family and religious constellations No great emotional feeling about drinking as such is particularly noticeable there have never been experiences with Prohibition, there are no total abstinence movements, there is no Dionysiac cult or worship of drinking It is held emotionally as more significant than salt or chocolate, but there is no great excitement about it

Members of this group do sneer at other groups that exhibit drunkenness Two final comments First, all members of this society drink, they do so hundreds of times every year, they use beer, wine, and distilled spirits, second, all evidence points to the conclusion that emotional maladjustments in this group are at the very least as common as they may be in any segment of American society This group may be called Orthodox Jews Alcoholism is practically unknown [1]

Second Example—A second American group may be described as follows The social functions of drinking are rather vaguely and somewhat defensively described, they concern drawing people, both family members and also complete strangers, together, often for purposes of 'fun,' often to allow relaxation from (rather than as in the preceding case closer adherence to) moral norms There is only an archaic symbolism for drawing man closer to deity, and this refers to such a specialized situation that it is not even considered to be "drinking" The rules and procedures are on occasion rather specific, but also show enormous variability so that a given individual may follow one set of rules with his family, another with business or professional associates, and a third on holiday occasions and show even different patterns when away from the home town

Sanctions for violations are extremely irregular, ranging from accepting laughter to violent physical attack Parents, employers, priests, physicians, and other agencies of sanction are most uncertain sources, both in formal statement and in actual behavior, many of them avoiding the issue whenever possible The custom shows marked variations by segments and subsocieties of the group, again adults, men, and wealthy persons tend to drink more frequently Some, however, do not drink at all, use of alcohol by women and children is suspect, and certain occupations are ordered not to drink at all (although acceptance of this sort of rule is surely irregular)

The custom is generally learned between the ages of 15 and 20 and accompanies the time of the troublous diminution of parental controls (as contrasted to the characterization of the time of learning in the preceding group) Sometimes the learning stems not from parents, ministers, physicians, elders, and teachers but from other adolescents, sometimes on trains, in cars, or in commercial places The custom is not significantly entwined with family and religious institutions, although there may be one set of drinking practices related to the family There is great emotional feeling about the problem on the mass level as well as by individuals, feeling that has run rampant for generations Activating the custom, especially by the young, is often attended with feelings of guilt, hostility, and exhibitionism and may occur as a secretive practice insofar as parents or employers or elders are concerned

The final comments—perhaps three quarters of the males over 15 years of age and perhaps over one-half of the females over 15 years of age use alcohol beverages, there being not too much use of wine, relatively greater use of beer by men, and use of distilled spirits The variation in frequency of use is broad, mostly in the range of 25 to 200 times a year, although information on the subject is scanty Second, the incidence of emotional and psychological disturbances is probably not exceptionally high, it may well be average or even less This group may be called the United States American of the northeast quarter of the nation —Protestant, middle-class, urban, white, from Anglo-Saxon background of three or more generations in this country Alcoholism certainly is not rare in this group Perhaps 3 to 7 of every 100 users of alcohol and five or six males to every female, most of them being between 35 and 55 years of age, are alcoholics

Third Example —A third social milieu, characteristic for perhaps a million and a half Americans, can be described as follows In this group the social function of drinking is officially stated to be (*a*) nonexistent and (*b*) if drinking occurs it is held to be disruptive, deteriorating, and disgusting The actual social function, among those who do drink, can only be stated in terms of those who do get together and imbibe, for them it is probably an important means for establishing their identity (as different) among themselves and for reinforcing adhesion of such a coterie Unless the total group should change its major viewpoint and practice (total abstinence) the social functioning of drinking can only be in the area of deviation or even departure from the group, it may allow one type of bridge to members of other groups and thus serve as a channel through which other sorts of change (business, politics, arts, etc) might be introduced

Functions of drinking for the individual will loom much larger than social functions when this group is compared to the other two Rules and procedures for drinking will be borrowed from other cultural milieux, by definition they cannot be home-grown products and cannot be accepted as rules and procedures by the group as such but only by the drinking individuals There are no sanctions for drinking and, only in one limited sense, against drinking (no matter how it is activated, by whom, when, in whatever manner, etc) —it is taboo

There is probably a great deal of variation (for which there is no evidence) in the practice of drinking according to the heterogeneous extrasocial models of this behavior, according to individual participants, and according to any sorts of differentiation that exist within the group (e g , wealth, occupation, location, educational achievement) The practice (it is only a custom in a most limited sense) is learned, insofar as the group is concerned, from improper, deviant members of the group, in hiding or away from the area The practice is at odds with at least the official position of every other institution or way of the group There is great emotional feeling against the practice Members of the group feel superior to groups that do drink and equate drinking with drunkenness, atheism, crime, disease, poverty, and immorality in general There is very little evidence about the extent of the practice Perhaps 25% of the men and 6 or 7% of the women should be counted as users of alcohol I know of no evidence about the prevalence of emotional disorders, but I have no reason to believe that it is high A guess might be allowed to the effect that it was lower than some abstract United States average From indirect knowledge and limited data, it would appear that the incidence of alcoholism in this group, the American Mormons, is very low It would also appear that the incidence of alcoholism among drinkers in this group is very high, i e , more than 3 to 7 out of every 100 drinkers [2]

Fourth Example —The fourth and last illustration is not drawn from the United States In this primitive South American society the social function of drinking alcohol beverages is so well understood that, somewhat paradoxically, it would be hard for the members to explain it—just as the social functions of eating in our society are probably for most of us beneath the level of conscious realization The social function of drinking for the group being described is getting together, enjoying life, identifying all sorts of achievements, events, and symbolic values, fulfilling all sorts of socially approved ways, enhancing status, and just 'being a human being' The rules and procedures are understood and activated by all Again the men tend to drink more, although perhaps not more frequently, wealth is viewed differently, and differences in wealth are less marked so that this comparison, noted in the other three groups is probably of less significance

Certain leaders of the group, comparable perhaps to our status of mayor, drink more frequently The society does not manifest many subsocieties or categories, and drinking differences on this level may not exist According to reports there is little violation of rules and procedures, and there are almost no instances of deviations from expectancy except by some individuals who were away for a few years (e g, in military service) Deviation would consist of drinking at the wrong time, drinking alone, etc

The custom is learned from childhood, and the practice itself generally takes place in full public view It is a practice almost inextricably entwined with major ways of life and social institutions In terms of the previous examples, there is not great emotional tension or excitement about drinking, certainly, feelings of guilt, hostility, anxiety, and the like are absent Apparently everybody drinks, both beer and distilled spirits They drink perhaps 100 to 200 times a year Drinking to the point of and beyond intoxication is a common if not the usual practice Alcoholism is apparently unknown, although, among those who have for a while been in the armed services or in industries in the big cities, the condition has been heard of, no word for such a condition exists in the language There has been no survey of the prevalence of emotional disorders (because the culture is so different from western civilization, many diagnostic labels and behavioral symptoms would hardly apply), but one feels from the descriptive material that, if a rate were established, it might be lower than for the three groups previously discussed [3]

Comment

These four examples, clearly oversimplified and often without sufficient data, serve to illustrate the view that there are various sociological "terrains' for the emergence of alcoholism and that the differences are significant for the greater or less prevalence of the condition They may help to illustrate the point that the background psychological factors considered important for alcoholism may not mature into that condition if the cultural conditions are negatively structured for such a development It is perhaps not unlikely for a Mormon woman for 45 years an average participant in that community to develop emotional problems, neurotic symptoms, or the like It is quite unlikely for her to adopt the use of alcohol to mitigate or mask such problems For the emotionally upset Orthodox Jew, such a development is even more unlikely For him or her there are such positive moral, religious, and family group values attached to use of alcohol that alcoholic behaviors would be similar to a Christian's adoption of the behavior of smashing altars as a means of gaining relief from guilt and anxiety Excessive eating, gambling, drug addiction, or compulsive work habits would be more likely channels for expressing symptoms in the case of the individual brought up with a well-instilled belief in the symbolic and sacred character of using alcohol beverages

On the other hand, for the young Mormon who is rebellious, who strongly rejects the controls of parents, church, neighbors, and the like, who can find in the larger society that surrounds Mormonism opportunities to achieve financial, occupational, esthetic and recreational satisfactions, and who needs to exhibit his new individual freedom, the use of alcohol beverages is a dramatically useful tool Unequipped with rules, models, sanctioning agents, realistic knowledge, and appropriate restraints or directions from related institutions about drinking but fully equipped with rebelliousness, many guilt feelings and anxieties, and needs to impress his newly found associates with non-Mormonism, especially as that means activation of what he has always known to be vices, this man is probably an excellent prospect for alcoholism A converse proof of the theory that the social situation of learning to drink is important for the appearance or nonappearance of alcoholism would call for a study of such situations among alcoholics no matter what group they came from Ullman's studies on this matter [4] certainly reinforce the theory

Lest the reader think that these social factors are being described as sufficient causes, let me say that there are rebellious Mormons who drank and did not become alcoholics There are probably cases of Mormon women who never left the community and who did become alcoholics Furthermore, the illustrations presented are of an extreme nature They are here used to indicate the nature of relevant sociological factors In most instances the impact of such phenomena will not be so definite The cultural and social background will not be as consistent as that of Orthodox Jew or Mormon For example, in almost all groups in the United States, women are so brought up, drinking by women is so sanctioned, and drunkenness in females is so punished that, even for members of the same group, alcoholism is less likely to appear among women than among men Put in different terms, other things being equal we would expect greater personality problems or more anomalous social experiences in the cases of 100 women alcoholics than among 100 alcoholic men

This discussion of a sociological aspect of alcoholism etiology is merely illustrative There are other sociological formulations that may help to explain the emergence, form, extent, accompaniments, etc, of this condition The purpose of this presentation is to indicate the utility of sociological data and methods for more effective understanding of some of the unanswered, troublesome questions faced by medical men In this instance, why are such differential rates of alcoholism found in different sociocultural groups? Physiological, psychological, and pharmacological approaches alone do not answer this question effectively

PROSTATECTOMY

Although prostatectomy is performed for either benign or malignant disease of the prostate, Cline[1] emphasizes the fact that the operation should not be done on patients with benign hypertrophy unless there is definite evidence of obstruction at the neck of the bladder accompanied by symptoms of urinary difficulty and in most cases residual urine. When such a condition develops, operation should not be delayed. Since a number of operative approaches are now available, each with its ardent enthusiasts, it has become necessary to establish some criteria for a successful operation. Bergman and co-workers[2] based their criteria for a successful operation on the immediate postoperative results, but others believe that long-range results must be considered in order to get a true picture of the relative success of a given procedure.

The first approach to be widely used was suprapubic or transvesical prostatectomy. Wormley[3] prefers this approach for benign prostatic enlargement if the hypertrophy is intravesical and the estimated weight of the prostate exceeds 50 Gm. This method has the advantages that the technique is relatively easy, the gland can be easily removed, bleeding in most cases is easily controlled, and the death rate of about 3% is as low as that associated with any other approach except the transurethral method. The end-results in most cases are excellent. Improvements in the technique of this operation have kept its popularity alive. Those who favor some other approach point to the following disadvantages: greater postoperative pain and shock (proponents claim that modern treatment of these conditions makes this an unimportant consideration in view of the long-range advantages), urinary leakage, and severe bladder spasm. Boyd,[4] an ardent enthusiast for suprapubic prostatectomy, reports only 2 postoperative deaths in a series of 100 cases. Both deaths were due to heart disease.

Wormley advises the perineal approach when the patient has calculous prostatism, and when the hypertrophy is intraurethral rather than intravesical. It has the advantages of a low death rate and minimal postoperative shock (hence it is preferred for patients who are poor surgical risks), and it offers dependent drainage and a more direct approach (an especial advantage in obese patients). On the other hand the operative technique is more difficult, there is danger of injuring the rectum, and postoperative incontinence of urine and impotence are more common than with the suprapubic approach.

The transurethral method is preferred for small sclerotic glands, median bar, inoperable cancer, intraurethral hypertrophy, and small median and lateral lobe enlargements.[3] This operation also has a low mortality rate and can be used on patients who are poor surgical risks, it can be performed in most cases with minimal shock to the patient, who can usually be discharged from the hospital less than eight days after operation. It has the disadvantage that recurrences are common, because it is difficult by this approach to remove the hyperplasia completely, and delayed hemorrhage, continued pyuria, and urethral stricture are the more common postoperative complications.

Another approach to the prostate is the retropubic method. Nelson[5] prefers it because he believes that it reduces the incidence of complications seen with the other three methods. It can be used on practically all patients, whether the pathological change is benign or malignant. Atherton and Atherton[6] prefer this approach when the patient has a cancer plus benign hypertrophy. Taylor and co-workers[7] compared the results of prostatectomy with the suprapubic and the retropubic approach and concluded that the latter gave better control of bleeding, fewer postoperative fistulas, smoother convalescence, and lower postoperative mortality. Klinger[8] prefers this method because, in addition to these advantages, the operation is performed under direct vision and is completely extravesical, healing is rapid, there is early resumption of voiding and absence of urinary drainage, the urine rapidly becomes clear, and the operation does not result in impotence. Watts[9] states that, like the other methods, this approach has its drawbacks, chief among which is difficulty closing the prostatic capsule after removing the gland. Others believe that the development of osteitis pubis is a troublesome complication with this method. Watts has described a modification that combines the advantages of the retropubic and suprapubic approaches, as he believes these are generally to be preferred to the perineal or transurethral route.

It can be seen that each of the four methods of removing the prostate has its adherents. Well-trained urologists are now competent to handle all four procedures, and the decision on which method to use in a given patient depends on the type and character of the protatic obstruction.

ORGANIZATION SECTION

FEDERAL MEDICAL LEGISLATION

First Session, 85th Congress

Loans to Nonprofit Hospitals

Representative Poage (D, Texas), in H R 1979, would authorize the Secretary of Health, Education, and Welfare to make loans for the construction of nonprofit hospitals Loans would bear an interest rate of not more than 3% and would have to be repaid in not more than 30 years The appropriation of 50 million dollars would be authorized This bill was referred to the Interstate and Foreign Commerce Committee

Hill-Burton Funds

Funds for Mental Health Center or Clinic—Senator Mundt (R, S D), in S 230, has introduced a measure which would make eligible for Hill-Burton hospital construction funds 'a nonprofit corporation or association which receives, from the State in which any such corporation or association is located or from any political subdivision of such State, any funds for the operation of a mental health center or clinic" At the present time grants are given for diagnostic and treatment centers when they are operated by governmental or public sponsors or corporations and associations that own and operate nonprofit hospitals

The Mundt bill would eliminate the requirement that a mental health center or clinic must have a connection with a nonprofit hospital This bill was referred to the Committee on Labor and Public Welfare

Grants to Governmental Hospitals Only—Representative Siler (R, Ky), in H R 3103, would amend the Hill-Burton construction act to permit grants to governmental institutions only, thus eliminating nonprofit sponsors, both sectarian and nonsectarian, from receiving such grants This amendment was referred to the Interstate and Foreign Commerce Committee

Unused Allotments of Funds—Senators Malone (R) and Bible (D) of Nevada, in S 559, would amend the hospital construction act so that states with a population of fewer than 700,000 according to the 1950 census could have 50% of unused portions of categorical grant funds transferred from one category to another The present categories are hospitals, health centers, diagnostic or treatment centers, hospitals for the chronically ill, rehabilitation facilities, and nursing homes The surgeon general would have to determine that the lapsed funds for a category existed because no approvable applications were pending This measure was referred to the Committee on Labor and Public Welfare

Hospital Construction (Indians and Non-Indians)—Senators Murray and Mansfield, in S 380, and Representatives Metcalf, in H R 2021, and Anderson, in H R 2380 (Democrats, Mont), have introduced identical bills which would authorize the surgeon general of the Public Health Service to make grants to states or political subdivisions thereof, or public or nonprofit associations to construct hospitals which would serve Indians and non-Indians alike A hospital is defined to include "public health centers and general, tuberculosis, mental, chronic disease, and other types of hospitals, and related facilities, such as laboratories, outpatient departments, nurses home and training facilities, and central service facilities operated in connection with hospitals, but does not include any hospital furnishing primarily domiciliary care'

The applicants would be required to give assurance that Indians would not be discriminated against in furnishing of services by or in connection with hospitals, and that the grants would be used to augment funds derived from other sources in constructing hospitals

The government could recapture a portion of the federal grant within 10 years if an eligible applicant ceased to be owner of the hospital or if any funds had been diverted, or if any assurance given in the application was not being carried out The Senate bill was referred to the Committee on Interior and Insular Affairs The House measures were referred to the Committee on Interstate and Foreign Commerce

Indian Hospitals

Representative Edmondson (D, Okla), in H Con Res 13, would provide that "no Indian hospital be closed or reduced in capacity or service unless and until the Secretary of the Interior shall have received from the head of the State agency responsible for public health in the State in which such hospital is located a certification that such closing or reduction will not create or intensify a shortage of hospital facilities in the area served, and no Indian hospital be closed or reduced in capacity if the infant mortality rate or the death rate from tuberculosis among the Indian popublation in the area served by such facility be higher than the similar rates among non-Indian population in the area This bill was referred to the Committee on Interior and Insular Affairs

Treaties and International Agreements

Senator Bricker (R, Ohio), in S J Res 3, and Representative Bow (R, Ohio), in H J Res 226, have introduced identical measures which would propose an amendment to the Constitution, reading as follows

'Section 1 A provision of a treaty or other international agreement not made in pursuance of this Constitution shall have no force or effect This section shall not apply to treaties made prior to the effective date of this Constitution

"Sec 2 A treaty or other international agreement shall have legislative effect within the United States as a law thereof only through legislation, except to the extent that the Senate shall provide affirmatively, in its resolution advising consenting to a treaty, that the treaty shall have legislative effect

"Sec 3 An international agreement other than a treaty shall have legislative effect within the United States as a law thereof only through legislation valid in the absence of such an international agreement

"Sec 4 On the question of advising and consenting to a treaty, the vote shall be determined by yeas and nays, and the names of the Senators voting for and against shall be entered on the Journal of the Senate"

Representatives Hiestand (R, Calif), in H J Res 43, and Lanham (D, Ga), in H J Res 59, have introduced similar measures The Hiestand proposal would require that

'Section 1 A provision of a treaty or other international agreement which conflicts with this Constitution, or which is not made in pursuance thereof, shall not be the supreme law of the land nor be of any force or effect

Sec 2 A treaty or other international agreement shall become effective as internal law in the United States only through legislation valid in the absence of international agreement

Sec 3 On the question of advising and consenting to the ratification of a treaty the vote shall be determined by yeas and nays, and the names of the persons voting for and against shall be entered on the Journal of the Senate

Sec 4 This article shall be inoperative unless it shall have been ratified as an amendment to the Constitution by the legislatures of three-fourths of the several States within seven years from the date of its submission"

Congressman Lanham would require that 'An international agreement, other than a treaty shall become effective as internal law in the United States only by an Act of the Congress Such legislation must be concurred by two-thirds of each House These measures were referred to the respective judiciary committees

Veterans' Medical Care in the Philippines

Senator Hill (D, Ala), in S 392, and Representative Bentley (R, Mich), in H R 3206, have introduced similar measures which would authorize the Administrator of Veterans' Affairs to enter into contracts and other arrangements that he deems necessary to provide hospital, medical, and domiciliary care including treatment in the Republic of the Philippines to the veterans entitled to such care

Hospital Facilities for Retired Officers and Enlisted Men

Senator Goldwater (R, Ariz), in S 542, and Representative Rhodes (R, Ariz), in H R 2174, have introduced identical measures which would provide that 'Whenever hospital facilities over which the Veterans' Administration has direct and exclusive jurisdiction, or other government facilities for which the Administrator of Veterans' Affairs may have contracted, are available, the Administrator shall furnish to retired officers and enlisted men, upon application, hospital treatment for diseases or injuries" The Senate measure was referred to the Committee on Labor and Public Welfare and the House measure to the Committee on Veterans' Affairs

Practical Nurse and Auxiliary Hospital Personnel Training

Representative Huddleston (D, Ala), in H R 2156, would authorize the appropriation of 5 million dollars annually under the Vocational Education Act so that the Commissioner of Education could make grants to states which would sponsor programs for the development of practical nurse and auxiliary hospital personnel training The states would contribute funds for such programs within a formula similar to the Hill-Burton Construction Act formula with the federal government's share ranging from 33⅓% to not more than 75%

The term 'practical nurse" is defined as "a person who is trained to care for subacute, convalescent, and chronic patients under the direction of a licensed physician or under the supervision of a registered professional nurse, or to assist a registered professional nurse in the care of acute illness

(b) The term 'auxiliary hospital personnel means persons working in hospitals under the general supervision and direction of graduate nurses and heads of departments and services, such as ward aids, nursing aids and assistants, and assistants in laboratories and clinics and dietary departments of hospitals"

A similar bill was enacted in the last Congress—an appropriation of 2 million dollars plus administrative costs This bill was referred to the Committee on Education and Labor

Social Security Amendments re Disability Benefits

Senator Langer (R, N D), in S 173, would amend the Social Security Act to eliminate the requirement that an individual must have attained 50 years of age or over before he would be eligible for disability benefits thereunder The present law requires that the covered employee must be at least 50 years of age before he is eligible to receive money payments The Langer amendment would make any person who has acquired an insured status by reason of making contributions for the required number of years eligible to obtain disability money payments if he became permanently and totally disabled, regardless of age This amendment was referred to the Committee on Finance

Appointment of Chiropractors in the VA

Representative Rogers (R, Mass), in H R 2178, proposes to authorize the appointment of chiropractors in the Department of Medicine and Surgery of the Veterans' Administration They must 'hold a degree of doctor of chiropractic from a school or college approved by the Administrator, be licensed to practice chiropractic in one of the States or Territories of the United States or in the District of Columbia, and have practiced chiropractic for a period of at least two years'

Senator Magnuson (D, Wash) introduced, in S 968, an identical bill and then amended it to include the provision that "whenever any person is entitled by law or regulation to receive medical care by or through the Veterans' Administration he shall, if he so elects, have the right to receive chiropractic care and the Chief Medical Director shall make available the services of qualified chiropractors' This bill was referred to the Committee on Labor and Public Welfare

Non Service Connected VA Hospital Care

Representative Teague (D, Texas), in H R 2196, by request, has introduced a measure which would give equal priority for service-connected and non-service-connected disability or injury for inpatient and outpatient VA care for those veterans who have a service connected disability which is 30% or more disabling This measure was referred to the Committee on Veterans Affairs

Medical Advisory Committee on Alcoholism

Representative Huddleston (D Ala), in H R 2220, would establish a Medical Advisory Committee on Alcoholism in the Department of Health, Education, and Welfare The members would be appointed by the President "after consultation with the American Medical Association and the Mental Hygiene Division of the United States Public Health Service At least two-thirds of the members of the Committee shall be physicians, each of whom is licensed to practice medicine in one of the States or Territories of the United States or in the District of Columbia, and whose interest in the problems of alcoholism has been manifested by his medical background, studies, education, and research in the field"

The functions of the committee would be '(1) To advise and cooperate with the United States Public Health Service (and particularly with its Mental Hygiene Division) in promoting education on alcoholism throughout the departments and agencies of the Federal Government,

'(2) to promote education on alcoholism throughout the several States, acting primarily through the State departments of health,

"(3) to advise on the establishment of clinics for the care of alcoholics,

'(4) to advise the departments and agencies of the Federal Government on the establishment of facilities for the care of alcoholics at various stages of the disease, and particularly to advise with respect to the different types of medical approach which are required for rehabilitation at the different stages,

(5) to advise educational bodies on medical matters connected with alcoholism, and to provide material for inclusion in the syllabus of the various educational institutions, and

'(6) to provide advice, from a medical, educational, community, and sociological point of view, regarding the care, treatment, and prevention of alcoholism throughout the country" This bill was referred to the Committee on Interstate and Foreign Commerce

Medical Care for Permanently Disabled Seamen

Representative Addonizio (D, N J), in H R 2374, would amend the Public Health Service Act to provide "Medical and other care to seamen becoming permanently disabled while on active service Under the present law, to be eligible for care in medical facilities operated by the Public Health Service, the applicant must be able to show that he has been employed for 60 days of continuous service on a licensed vessel of the United States, part of which time must have been during the 90 days immediately preceding application for medical care Under the Addonizio proposal persons who have at any time acquired permanent disabilities while employed as seamen would be eligible for care for the rest of their lives This amendment was referred to the Interstate and Foreign Commerce Committee

Medical Care for Persons Engaged on U S Vessels — Delegate Bartlett (D, Alaska), in H R 2395, would amend the Public Health Service Act to provide medical care for all persons engaged on board a vessel in the care, preservation, or navigation of such vessel, thus including owners and operators of vessels as well as employed seamen Owners and masters are not at present eligible for such care This bill was referred to the Interstate and Foreign Commerce Committee

Vocational Rehabilitation of the Homebound

Representative Bentley (R, Mich), in H R 2398, would amend the Vocational Rehabilitation Act to authorize the application of 2 million dollars annually for 6 years from which the Secretary of the Department of Health, Education, and Welfare would 'make grants to States and public and other nonprofit organizations and agencies for the purpose of—

(A) establishing methods and techniques for the use of other states, organizations, and agencies in understanding the size, essential characteristics, and needs of the homebound population

(B) developing effective and economical methods for coordinating available resources to provide the services needed to achieve the highest possible level of useful activity for each physically handicapped individual who is homebound

'(C) furnishing data on which reliable material estimates may be projected and the future role of the Federal Government may be determined in meeting the needs of the physically handicapped individuals who are homebound' This was referred to the Education and Labor Committee

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

TWO NEW STATE SCHOOLS OF MEDICINE—UNIVERSITY OF MISSISSIPPI AND UNIVERSITY OF MISSOURI

The University of Mississippi School of Medicine, first created by an act of the board of trustees of the University in June, 1903, was located on the campus of "Old Miss" at Oxford During the next six years it offered the first two years of a four-year medical curriculum In 1909-1910, a clinical department was established at the State Charity Hospital of Vicksburg but was discontinued after one session In 1950, the Mississippi legislature passed an enabling act and an act making an appropriation to establish a four-year school of medicine to be located at Jackson as part of the University of Mississippi and a teaching hospital to be operated as part of the school Additional funds for construction of the hospital were provided by Hinds County and by the federal government

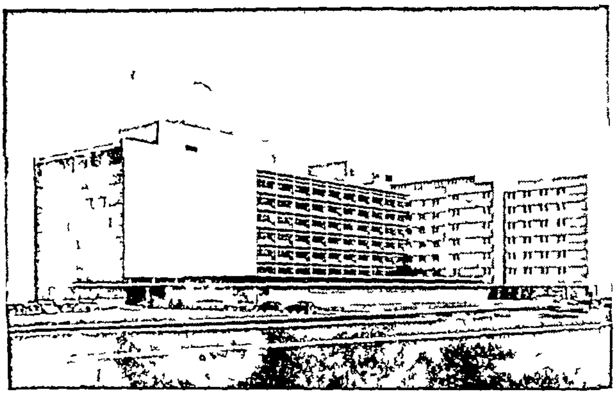

Fig 1 —University of Mississippi School of Medicine and University Hospital Jackson

The University of Mississippi Medical Center, consisting of the School of Medicine and the University Hospital (fig 1), was completed in the summer of 1955 The personnel and equipment of the two-year basic medical science school at Oxford were moved to the new building in Jackson in time for the beginning of the academic year 1955-1956 It will graduate the first class in June, 1957

The University of Missouri School of Medicine was originally built upon the medical department of Kemper College (McDowell Medical College), founded in St Louis in 1840 This was the first medical school established west of the Mississippi River, and in 1845 it became a department of the University of Missouri Ten years later the school was discontinued, and in 1872 it was reestablished on the university campus in Columbia, where it offered the two year program characteristic of most medical schools at that time In 1891, the curriculum was increased to three years and in 1899 to four years The last two years of the curriculum were discontinued in 1910 because of the inability to finance expansion necessary for adequate teaching of clinical subjects From 1910 to 1955 the university maintained the first two years of a regular medical course with its students transferring to other institutions for their clinical training In 1951, the legislature of Missouri appropriated funds to enable the University of Missouri to undertake expansion to a full four-year program leading to the degree of doctor of medicine

Additional appropriations were made by the legislature in 1953 for construction of a new university hospital, medical sciences building, and nurses dormitory These structures (fig 2) have been completed and have been occupied during recent months The curriculum for the third year was activated in 1955 1956, and the University of Missouri will graduate the first class from this new four-year school in June, 1957

Fig 2 —University of Missouri School of Medicine and University Hospital, Columbia

POSTGRADUATE COURSES

The following postgraduate courses have been reported to the Council

The Ear, Nose, and Throat Clinics and Seminars, sponsored by the University of California Medical Center in San Francisco, will be held May 24-25, 1957, for physicians in general practice and part-time specialty practice The 14 hours of instruction will include operative surgery, lectures, open question periods, and motion pictures The fee will be $40

Beginning June 11, 1957, the University of California Medical Center in San Francisco will hold a continuous Pediatric Postgraduate Course, emphasizing endocrinology and related problems in the practice of pediatrics The four days of lecture will be offered to physicians in general practice and part-time specialty practice for a fee of $60

MEDICINE AND THE LAW

This is the ninth in a series of article dealing with medical professional liability An editorial (page 360) and a chronological résumé (page 364) appeared in The Journal, *Feb 2 One of the preceding articles has been published each week in* The Journal *beginning Feb 9, 1957, except in the April 20, April 27, and May 4 issues* —Ed

PROFESSIONAL LIABILITY AND STATUTES OF LIMITATION

One of the purposes of the law is to furnish a forum which persons who have suffered a wrong at the inds of another may present facts for adjudication by judge or jury Ideally this should be done as prompt- as possible after the wrong has been suffered be- use necessary witnesses may die or move away, ius making the presentation of facts, by both the laintiff and the defendant, difficult or impossible ealizing that a defendant needs some protection gainst a plaintiff who might purposely withhold filing uit until the defendant's witnesses have disappeared, tate legislatures have enacted laws requiring injured ersons to bring suit within a specified period of time fter they have received their alleged injuries These aws, known as statutes of limitation, limit the time ithin which a person may commence an action for ersonal injuries, breach of contract, slander and libel, tc They are founded upon the general experience hat claims that are valid are not usually allowed to emain neglected

As is true of so many other laws, the provisions of statutes of limitation vary considerably from state to state, not only as to the length of time allowed to bring various types of actions but also as to when the time starts to run, factors that prevent the time from unning, types of action covered, etc

As the accompanying table indicates, every state has enacted a statute relating to the time within which an injured patient may sue a physician for professional misconduct In only 17 states however, does the statute refer specifically to malpractice or professional liability of physicians, in the others such suits are covered by the statute applicable to torts in general or to all personal actions, whether in tort or contract The important thing to physicians is that a limitation statute exists in every state, and each physician should know the length of time applicable to such actions in his jurisdiction In addition to knowing the limitation period applicable to professional liability cases arising out of tort or out of the implied contract created by the mere existence of the physician-patient relationship, the physician should remember that he may also be sued for breach of a specific promise to cure, if he has been foolish enough to make one In such a case, the period of limitation applicable to suits on an oral or written contract will govern the situation The period for filing suit on a written contract, and on an oral contract in some states, is almost always longer than that for filing suits for torts in general The period of limitations for contracts, however, will apply to a professional liability case only when there has been a specific promise to cure In other cases, the limitation period prescribed for actions against physicians for professional liability or negligence has been held to apply notwithstanding the fact that the complaint in a particular case is in the form of an action on a contract

Factors That Prevent Statutes from Running

In addition to knowing the basic limitation period applicable to professional liability cases in his state, each physician should also be cognizant of certain conditions that prevent the statute from running against the claimant These situations arise by virtue of statute, rather than from the common law, and again they vary from state to state Perhaps the most common factor that prevents the running of the statute is infancy In 44 states and the District of Columbia, if the alleged injury is to a minor the statute does not begin to run until after the person reaches his majority, usually 21 years of age for males and 18 for females In most instances the basic statute then applies, although in a few instances the time applicable after minority terminates is shorter than the general statute

Another important factor that may have the effect of tolling the statute is the fradulent concealment of a cause of action by a wrongdoer This is especially true in those cases in which the plaintiff's injury did not manifest itself until some years after the negligent act was committed A foreign body left in a patient after surgery may not cause trouble until after the statutory period has run If there is any evidence that indicates that the physician knew of the presence of the foreign body but did not so advise the patient, some courts have held that there has been a concealment of the cause of action by the physician and that the statute does not start to run until the plaintiff discovered the injury, or in the exercise of reasonable care should have discovered it

Other factors that sometimes effect the running of the statute are the absence of the patient from the jurisdiction and the fact that the patient is insane It should also be noted that in some states the provisions of the Wrongful Death Statute might seem to affect an extension of the statute of limitation That is not exactly what happens, however When an injured patient dies, the representative of his estate is granted a certain length of time in which to file a suit for damages on behalf of the estate This time begins to run, of course, with the time of the death The physician is thus liable to be sued for a period longer than the period of limitations for professional liability actions, not because the period for filing such an action is increased but because the death of the patient actually created a new cause of action, which is subject to a new period of limitation Periods of limitation stated in wrongful death acts differ from state to state, just as do periods limiting the time within which professional liability suits may be started Therefore, here again the physician must familiarize himself with the provisions of the law in the state in which he practices

Statutes of Limitation

State	No of Year Statute of Limitation Apply: Mal practice (Tort)	Mal practice (Tort or Contract)	Oral Contract	Written Contract	Assault and Battery	Wrongful Death Action	States in Which Statute Refers Specifically to Malpractice or Professional Liability	States in Which Statutes Limitation Run: From Time of Negligent Act	From Termination of Physician Patient Relationship	From Time of Discovery of Injury	From Time Cause of Action Accrues	From Termination of Treatment	State in Which Infancy Tolls Statute

Start of Limitations

In addition to knowing when the statute does not run, it is also helpful to know when it does run or, more specifically, when it actually starts to run Here, once more, there is considerable variation as the table indicates This table was prepared on the basis of a survey of the statutes of each state conducted by the Law Department If the results differ somewhat from other tabulations, it is because some interpretations must be made and there is often room for a difference of opinion In 25 states the statute starts to run at the time the negligent act was allegedly committed or at the time the accident happens In five states the statute runs from the time the injury is discovered or from the time the injury should or could have been discovered if the plaintiff exercised a reasonable degree of alertness Three states start counting the time from the termination of the physician-patient relationship and three other states from the time the treatments, if there is a series of them, terminate One state counts from the time the cause of action accrues Perhaps this should really be added to the number of states using the time of the negligent act as the starting point, although the two do not necessarily coincide Finally, it will be noted that no classification was made for 11 states and the District of Columbia This is because in those jurisdictions no clear decision as to when the statute starts to run could be reached from the wording of the statutes or court cases covered by the survey

Twenty-nine states and the District of Columbia have enacted statutes of limitation relating specifically to actions for assault and battery in addition to those relating to professional liability or personal injury An action based upon an unauthorized operation, for example, may also be an assault and battery In those states in which the statutory period for actions for assault and battery is less than for professional liability and there are 15 of them, the question naturally arises as to which statute would apply It is the policy of the law to protect a cause of action wherever possible, and it is therefore safe to conclude that if there is a choice the court will adopt the statute most favorable to the plaintiff

Importance of Statutes of Limitation to Physicians

Having considered the purpose of the statutes of limitation, the time limits in each state, the factors that prevent or delay the running of the statute, and the factors that determine the time from which the statute runs, consideration must now be given to the ways in which the statutes of limitation are important to physicians, especially with reference to professional liability There are two in particular

As the length of service and the volume of a physician's practice increases, the need for storage space for his files becomes a major problem How long should these records be kept? It is possible to suggest at least a minimum guide This minimum guide is the statutory period of limitations for professional liability actions in the particular jurisdiction In view of the important part that a physician's records play in the defense of such an action, they should not be disposed of before the time has passed within which he may be sued Furthermore, even though no suit is filed against the physician, it is often essential to the interests of the patient that such records be available for the prosecution of a personal injury or workmen's compensation claim Thus, the period of limitations for professional liability actions, and for personal injury actions generally, represents a definite minimum period during which a physician should preserve his office records Physicians taking care of young people or children, pediatricians and obstetricians especially, should remember that the statutory period does not run in most states until the patient becomes of age Parenthetically, it might be pointed out here that the development and improvement in recent years of the process known as microfilming has proved to be an answer to the records-maintenance problem There is no reason why physicians may not utilize the advantages offered by such a process If that is done, hundreds of patients records may be preserved in less space If reference must be made to them later or if they are needed for use in court on some future occasion, they are readily available

The second thing that makes statutes of limitation particularly important to physicians relates to the subject of income From time to time it becomes necessary for a physician to utilize the facilities of the law for collecting from his patients—in other words he must sue for a fee Just as a patient has a certain length of time in which to file a professional liability action so too must a physician file a suit to recover a fee within a certain period However, a suit for a fee is generally a suit on contract, oral and implied, whereas a professional liability suit is usually a tort action

An inspection of the table reveals that in 32 states the statutory period fixed for professional liability actions differs from that fixed for suits based on an oral contract It shows, further, that in only one of those states is the statutory period less for a suit on a contract In all others the period within which one may sue on a contract is from one to nine years longer than the professional liability period Thus, if a physician should sue a patient for a fee during the limitation period for the filing of professional liability suits, the patient may file a counterclaim for damages as an affirmative defense to the suit for fees The courts quite generally hold, however, that a counterclaim is an affirmative action, not a matter of pure defense and that, if the statute of limitations has run on the affirmative action, it may not be reinstated by setting it forth as a counterclaim To hold otherwise would frustrate the purpose of compelling claimants to seek prompt enforcement of their claims This means, therefore, that if a physician withholds the filing of a suit to recover a fee until the statutory period for a professional liability action has passed the issue will be limited solely to the amount and reasonableness of the fee charged and whether or not it has been paid

A physician may, therefore, prevent at least some professional liability difficulties by being aware of the provisions of the statutes of limitation in his state

MEDICAL NEWS

ARKANSAS

Grant for Mentally Retarded Children—The Children's Bureau has made a grant of $38,780 to the Arkansas State Board of Health for a special project for mentally retarded children The funds were authorized as part of one million dollars designated by Congress in 1956 for mental retardation programs throughout the country The money will be used to help establish a child development center at Little Rock, to which children from all over the state may be referred Emphasis will be on diagnosing the extent of retardation in the child and on counselling parents on how to help the child develop to his maximum potential

ILLINOIS

Annual State Surgical Meeting—The annual meeting of the Illinois Surgical Society will be held May 20 The clinics, to be held at 8 a m, at Cook County Hospital, Harrison and Wood Streets, Chicago, will include two symposiums "Surgery of the Biliary Tract and Pancreas," moderated by Dr Raymond W McNealy associate professor of surgery, emeritus, Northwestern University Medical School, Chicago, and "Care of Fractures," by Drs George L Apfelbach, associate professor of orthopedic surgery, emeritus, Edward L Compere, professor of orthopedic surgery, and Robert T McElvenny, assistant professor of orthopedic surgery, Northwestern University Medical School At the scientific meeting, 7 30 p m at the University Club, Michigan Avenue and Monroe Street, Dr George A Hallenbeck, assistant professor of surgery and physiology, University of Minnesota Graduate School, will present "Peptic and Gastric Ulcer Surgery," with discussion by Drs Lester R Dragstedt, Chicago, Karl A Meyer, Chicago, Walter L Palmer, Chicago, and Tilden C Everson, Chicago The medical profession is invited to all sessions

MICHIGAN

Internists Organize—Fifty-three Michigan specialists in internal medicine from all over the state met in Lansing, Feb 23, to discuss the advisability of forming an organization to best approach the problems of their specialty It was decided to form the Michigan Society of Internal Medicine' Those present became the founding members and, after adopting a constitution, elected officers The objectives of the society are to unite the qualified internists of the state in a representative organization for the furtherance of the practice of internal medicine, to study the scientific, economic, social and political aspects of medicine in order to secure and maintain the highest standards of practice in internal medicine, and to cooperate with other organizations of like purposes The organization voted to join the American Society of Internal Medicine All the founders are diplomates of the American Board of Internal Medicine Newly-elected officers are president, Dr James W Hall Jr, Traverse City, vice-president, Dr Michael C Kozonis, Pontiac, secretary treasurer, Dr Ross V Taylor, Jackson

MISSOURI

Personal—Dr Clarence D Davis, formerly professor of obstetrics and gynecology at the University of Missouri School of Medicine, Columbia, has been appointed associate professor of obstetrics and gynecology at the Yale University School of Medicine, New Haven, Conn ——Dr Orval R Withers of Kansas City, Mo, has been named president of the American College of Allergists ——Dr Robert B King has been appointed professor of surgery, Syracuse University College of Medicine, Syracuse, N Y, effective June 1 He is presently assistant professor of neurosurgery, Washington University School of Medicine, St Louis ——Dr Walter J Burdette, professor of clinical surgery, St Louis University School of Medicine, Columbia, and director of the St Louis University surgical service at Veterans Hospital has been awarded two grants totaling $24,895 by the American Cancer Society Dr Burdette is conducting research on the isolation of a new hormone which may be useful in the treatment of cancer

New Rehabilitation Institute—Washington University, St Louis, announces plans for a new rehabilitation institute to serve disabled persons in the St Louis metropolitan area It will also train personnel in rehabilitation procedures, develop new methods of treatment, and carry on an active research program relating to chronic disabilities The new building, which will be located on Euclid Avenue, between McMillan Hospital–Oscar Johnson Institute and the Washington University Clinics, will house the departments of physical and occupational therapy now located in other buildings in the Washington University Medical Center Dr Robert E Shank, professor of preventive medicine since 1948, will be director of the institute Defects to be treated will include hemiplegia, paraplegia, amputations, cardiac disabilities, muscular dystrophy, cerebral palsy, alcoholism, and speech and hearing difficulties Construction of the air-conditioned building is slated to begin before next July The cost will be about $675,000 In addition to funds given by the late Mrs Irene Johnson, for whom the institution will be named, a Federal grant of $114,000 was made in September under terms of the Hill-Burton Act Other support for teaching programs has come from the National Foundation for Infantile Paralysis

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals education, and public health Programs should be received at least three weeks before the date of meeting

MONTANA

Western Association Meeting in Missoula—The Western Montana Medical Association invites all physicians in this region to attend the Western Montana Medical-Surgical Conference June 29 at the Florence Hotel, Missoula Principal speakers will be Dr William R Christensen, professor of radiology, University of Utah College of Medicine, Salt Lake City, Utah, and Dr Lester R Dragstedt, professor of surgery, University of Chicago Topics to be considered include pathogenesis and treatment of gastric and duodenal ulcer, the solitary pulmonary nodule, anesthesiology, congenital heart disease, neurosurgical relief of intractable pain, radiation safety in the doctor's office, and flat feet The program has been authorized for eight hours of credit by the American Academy of General Practice A special ladies' program is planned, and a cocktail hour will be held at 5 30 and a dinner dance at 6 30 p m

NEW YORK

Appoint Surgery Department Director—Dr Charles L Eckert, formerly associate professor of surgery and director of tumor services at the Washington University School of Medicine, St Louis, was recently appointed chairman of the department of surgery at Albany Medical College and surgeon-in-chief to the Albany Hospital, to succeed the late Dr Eldridge Campbell Dr Eckert previously served as an affiliate in surgery at Barnes and St Louis Children's Hospital and at St Louis City Hospital and as consultant in surgery to the Veterans Administration Hospital, St Louis, and area consultant in surgery to the Veterans Administration

Dr Lippschutz Honored—A $90,000 endowment was recently presented by an anonymous local donor for a chair in clinical cardiology in the University of Buffalo School of Medicine Dr Eugene J Lippschutz, director of the cardiovascular section of the department of medicine at the Buffalo General Hospital, Buffalo, has been appointed to fill the chair, which has been assigned to the Buffalo General Hospital Dr Lippschutz, whose appointment became effective Jan 1, has been promoted from associate clinical professor to associate professor in the department of medicine The university will apply the grant over a five-year period as follows $12,000 each year for the professorship and $6,000 each year to cover additional expenses in conjunction with the research conducted

New York City

Harvey Lecture—The 10th and final Harvey Lecture in the present series will be delivered June 6, 8 30 p m, at the New York Academy of Medicine, 103rd Street and Fifth Avenue by Dr Carl J Wiggers, Bunts Educational Institute, Cleveland Clinic, Cleveland, whose subject is "Harvey Tercentenary"

Hospital News—An integrated department of cardiology has been established at The Mount Sinai Hospital under Dr Charles K Friedberg, who will serve as cardiologist to the hospital and attending physician for cardiology The cardiology department, a division of the department of medicine, will include and coordinate all cardiac groups and their clinical and research activities A comprehensive residency and clinical fellowship program is being established

Ira I Kaplan Lecture—The annual Ira I Kaplan lecture sponsored by the Radiation Therapy Alumni of Bellevue Hospital will be held in the Auditorium of Bellevue Hospital May 23, 5 p m A symposium on the physics and economy of isotopes and supervoltage will be held, with E Dale Trout, B S, Milwaukee, Wis, Dr Ruth J Guttmann, assistant professor of radiology, Columbia University College of Physicians and Surgeons, New York, and Dr Sidney M Silverstone, radiologist, New York City, serving as panelists

PENNSYLVANIA

Dr Leopold Receives Holmes Award—Dr Irving H Leopold, chairman, department of ophthalmology, University of Pennsylvania Graduate School of Medicine, Philadelphia, and director of research at the Wills Eye Hospital, Philadelphia has been named recipient of the 1957 Edward Lorenzo Holmes Memorial Award of the Institute of Medicine of Chicago

Dr Leopold will receive the award and speak at a joint meeting of the Chicago Ophthalmological Society and the Institute of Medicine on May 20

General Practitioners Meeting—The ninth annual Pennsylvania Academy of General Practice convention will be held at the Benjamin Franklin Hotel, Philadelphia, May 26-29 Dr Robert A Davison, head, department of general practice, University of Tennessee College of Medicine, Memphis, will present "Organization of Department of General Practice in Medical Schools," and a forum, "Diverticulitis, Diverticulosis, and Carcinoma of the Colon," will be moderated by Dr Lewis K Ferguson, professor of surgery, Woman's Medical College of Pennsylvania, Philadelphia A panel discussion, x-ray films, and medical and surgical treatment conference will be conducted by Drs Thomas A Johnson, professor of clinical gastroenterology, and Arthur Finkelstein, professor of radiology, University of Pennsylvania Graduate School of Medicine, Philadelphia Question and answer periods will follow presentation of papers in the morning and afternoon sessions Information may be obtained from Dr Edward J Kowalewski, Chairman, Publicity and Press of the Program Commission, Pennsylvania Academy of General Practice, 115 N 9th St, Akron, Pa

Philadelphia

Establish Charitable Foundation—The Physicians Square Club of Philadelphia has established a nationwide charitable foundation, which will extend educational and scholarship aid to orphans and assistance to widows of members of the medical profession and also seek to encourage medical research Dr D Barton Gelfond is president of the club, which is composed of physicians who are members of the Masonic Order A temporary board of trustees has been named with Dr Joseph B Wolffe, medical director of the Valley Forge Heart Hospital near Norristown, as president, Drs Jack S Ersner and George Rosenbaum, vice-presidents, Dr Matthew S Ersner, secretary, and Dr

Benjamin O Oliver treasurer The foundation will derive its funds from members of the Physicians Square Clubs throughout the country and from the medical profession

Student Loan Fund—A student loan fund in the amount of $11,500 has been established by Mrs Rose Strick at the Temple University School of Medicine as a 'living monument' to her husband, the late Frank Strick, industrialist Allocations from the gift, which is to be known as the Frank and Rose Strick Loan Fund, will be recommended by Dr William N Parkinson, dean of the school of medicine Students in need of financial assistance will receive $500 during a single academic year If necessary, a renewal may be arranged for another term Loans are to be repaid by students within six years after graduation

VIRGINIA

Personal—Dr Carl J Carter, of Fairmont, has been named superintendent of Fairmont General Hospital, as of March 1, succeeding Dr Philip Johnson who served as head of the institution since 1947

Annual Scientific Assembly—The seventh annual scientific assembly of the Virginia Academy of General Practice will be held at the Hotel Roanoke Roanoke, May 23-26 Among the speakers and their topics will be

Physiological Basis for Current Therapy of Degenerative Vascular Disease in Diabetes Mellitus Henry T Ricketts University of Chicago
Fat Cholesterol and Coronary Heart Disease Norman Jolliffe, New York City
Can Atherosclerosis be Reduced in the United States Howard B Sprague Brookline Mass

A panel discussion on the use of various types of insulin in the management of diabetes mellitus including the oral hypoglycemic agents, and the Nemours Foundation symposium on the handicapped child are featured Exhibits, a dinner dance, and a golf tournament at the Roanoke Country Club are scheduled For information write the Virginia Academy of General Practice, 1105 W Franklin St, Richmond 20

WEST VIRGINIA

Personal—Dr Azby A Milburn has been appointed by Governor Cecil H Underwood as acting superintendent of Weston State Hospital, Weston He succeeds Dr H Sinclair Tait, who resigned to accept appointment as senior psychiatrist at the Regional Office of the Veterans Administration in Wheeling

Ophthalmologists and Otolaryngologists Meet—The 10th annual meeting the West Virginia Academy of Ophthalmology and Otolaryngology will be held at the Greenbrier in White Sulphur Springs May 31-June 1 The scientific sessions will be held during the mornings with the afternoons left open for recreational activities The scientific program includes "Evolution of Vision,' by Dr Joseph Krimsky, chief, eye, ear, nose, and throat department, Veterans Administration, Huntington, and Eye Disturbances in Relation to Nasal Sinus Diseases," and Dacryocystorhinostomy Roentgenogram of the Optic Foramen by Dr Henry M Goodyear, professor of otolaryngology, University of Cincinnati College of Medicine, Cincinnati Roundtable discussions, 'When to Operate in Glaucoma, Ear, Nose and Throat Anesthesia," 'Scleral Resection and Buckling, and Ear, Nose and Throat Radiology,' are scheduled Dr Wilbur F Shirkey, Charleston, will be installed as president of the academy at the business meeting He will succeed Dr William F Beckner, of Huntington

GENERAL

Personal—Dr Gunnar Dybward, director, Child Study Association of America since 1951, has been named executive director of the National Association for Retarded Children

Winners of Leukemia Awards—The Leukemia Society, Inc, New York City, recently presented the Robert Roesler de Villiers awards under the society's contest III to Dr Leon Orris Jacobson, Chicago, and to John F Loutit, D M, F R C P, Steventon, Berks, England Participants at the presentation ceremonies included Drs Frank L Babbott, New York City, Leona Baumgartner, New York City, and William B Castle, Boston

Pathologists Meet in Baltimore—A joint meeting of the Middle Eastern Region of the College of American Pathologists, the Washington Society of Pathologists, the Maryland Society of Pathologists, and the Pathology Section, Baltimore City Medical Society is scheduled for May 26 in the auditorium, Veterans Administration Hospital, Baltimore At 5 p m a lymph node seminar will be conducted by Dr R Philip Custer, director of laboratories, Presbyterian Hospital, Philadelphia Seminar slides ($5 00) may be obtained from Dr Paul F Guerin, 700 Fleet St, Baltimore 2

Announce Hematology Fellowship—The Hematology Research Foundation invites applications for the Ruth Berger Reader fellowship for research in blood diseases in the academic year 1957-1958 The stipend for the fellowship is $3,000 a year with the option to renew Application from a scientist doing research on thrombotic thrombocypenic purpura, if such is available, would be welcomed The foundation also invites applications for grants-in-aid for the purpose of hemotologic research for the period of one year Applications must be submitted no later than May 30 to Hematology Research Foundation, 64 W Randolph St, Chicago 1, Ill Nine copies of application are requested (Application forms for fellowship or grants are available upon request)

Pediatricians Meet in Seattle—The annual spring meeting of the North Pacific Pediatric Society in association with the American Academy of Pediatrics will be held at the Olympic Hotel, Seattle, May 9 11 The Walter B Seelye Lecture will be given by Dr Amos Christie, 4 p m, May 9, in the auditorium of the University of Washington School of Medicine Guest speaker at the dinner May 10 will be Elof Götelander, director of public relations, Karolinska Institute, Stockholm The presidential address will be given by Dr Norman W Murphy, president of the society Panel discussions will be held following presentation of the formal papers at the general sessions A dinner dance will be held May 11 For information write A C McGinnis, 1427 I St N W, Washington 5

Goiter Association Meets in New York—The American Goiter Association will meet at the Hotel Statler, New York City, May 28-30 Topics to be presented by foreign authors include "T S H Discharge of Radioiodine from Thyroid Nodules in Vitro," by Selwyn F Taylor and B Moffitt, London, England, and "Serum Protein Abnormalities in Thyroid Disease," by D P Morgan, R Bird and R Greene, Hampstead, England The presidential address will be delivered by B M Dobyns, associate professor of surgery, Western Reserve University School of Medicine, Cleveland The Van Meter prize essay will be delivered May 29 A joint session with the Endocrine Society will be held May 30 at the Hotel New Yorker At that time R Pitt-Rivers, D Hubble, and W H Hoather, London England, will speak on "Distribution of Thyroidal Iodine in Some Nodular Goiters" For information write Dr John C McClintock, American Goiter Association, 149½ Washington Ave, Albany 10, N Y

Cardiovascular Research Awards—A broad range of studies in the field of heart and blood vessel diseases will be undertaken by 155 scientists recently named by the American Heart Association to receive $977,000 in research awards Major targets of these studies, to be conducted in the 12 months beginning July 1, will be the causes of coronary heart failure and high blood pressure and further development of artificial heart-lungs to facilitate dry-field surgery inside the heart The new awards provide differing levels of support Three are lifetime career investigatorships with $25,000 a year set aside to cover the stipend and help support the laboratory of selected individuals of outstanding scientific achievement and ability Eighty are established investigatorships, with $6 000-$9 000 a year awarded for five-year periods (subject to annual review) to highly-qualified scientists conducting independent research Seventy-two are research fellowships, intended to help young scientists prepare for research careers under experienced guidance Given for one- or two-year periods they provide stipends of from $3 500 to $6,000 a year

Influenza Outbreak—The following information appeared in the U S Public Health Service morbidity and mortality weekly report of March 8 Dr Klaus Hummeler, Children's Hospital, Philadelphia, reports that the virus isolated in the outbreak of influenza in a boys' school in New Jersey has been identified as influenza A-prime Dr Arthur M Washburn, Arkansas Board of Health, has reported that outbreaks of influenza-like disease have been reported in contiguous counties in eastern Arkansas No reports of laboratory confirmation of diagnosis were made At the time of this report, only localized epidemics of influenza, confirmed by isolation of virus or serologic tests, had been reported The first of these occurred in December in recruits stationed at Great Lakes Naval Training Station The second occurred in mid-January in El Paso County, Colorado, and the third was reported from Memphis, Tenn, late in January Scattered cases confirmed by serologic tests were reported in military personnel in the Norfolk, Va, area The first confirmed outbreak in civilians this winter was reported early in February in a university in Michigan, and the second about the middle of the month in the boys' school in New Jersey All the outbreaks have been identified as influenza A-prime virus infections

LATIN AMERICA

Drug Control Service in Brazil—A Federal Drug Control Laboratory and Service has been established in Brazil to apply the appropriate controls of drugs imported or manufactured in that country and offered for sale At the request of the Brazilian government the Pan-American Sanitation Bureau has provided a consultant to advise the director of the laboratory and service and to assist in its establishment and operation, in the development of field services, and in the revision and formulation of legislation The director of the laboratory is Dr Raymundo Moniz de Aragão

FOREIGN

Heart Symposium in Freiburg—A symposium on the functional diagnosis of the heart will be held under the direction of Prof Ludwig Heilmeyer, professor of internal medicine, at the medical clinic of the University of Freiburg, Freiburg im Breisgau, Germany, June 6-8 The subjects to be discussed are the importance of electrocardiography and vectocardiography, roentgenology, and spiroergometry and other methods of functional diagnosis The number of participants will be limited Information can be obtained from Dr H Klepzig, Medical University Clinic, Freiburg im Breisgau, Hugstetter Strasse 55, Germany

Harvey Tercentenary Congress—The Harvey Tercentenary Congress will be held June 3-7 at the Royal College of Surgeons, London, sponsored by the International Congress on Circulation Topics of discussion include knowledge of the circulation from the 17th-20th centuries, the role of the heart in the circulation, the results of cardiac surgery, and coronary, pulmonary, fetal and pulmonary circulation Registration fee is £10 ($28) The congress will be followed by a conference June 8 on the more personal and biographical aspects of William Harvey's life at his birthplace, Folkestone, Kent, and will include a visit to Canterbury Cathedral Details may be obtained from Congress Secretary, 11 Chandos St, Cavendish Square, London W 1, England

CORRECTION

Diagnosis of Schistosomiasis—Dr Benjamin W Warner has written THE JOURNAL saying that the words "and Balantidium coli," in the left-hand column, 11 lines from the bottom of page 1323 of the April 13th issue, should have been deleted, as this was an incidental infection not pertinent to the report

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

ALABAMA *Examination* Montgomery, June 18-20 Sec Dr D G Gill State Office Bldg Montgomery 4

ARKANSAS * *Examination* Little Rock June 13-14 Sec, Dr Joe Verser Harrisburg

CALIFORNIA *Written Examination* San Francisco June 17-20, Los Angeles Aug 19 22 Sacramento Oct 21-24 *Oral Examination* San Francisco June 15 Los Angeles August 17, San Francisco Nov 16 *Oral and Clinical for Foreign Graduates* San Francisco June 16, Los Angeles, Aug 18, San Francisco Nov 17 Sec, Dr Louis E Jones, 1020 N St, Sacramento 14

COLORADO * *Examination* Denver, June 11-12 Final date for filing application is May 13 Exec Sec, Miss Beulah H Hudgens 715 Republic Bldg, Denver 2

CONNECTICUT * *Homeopathic Examination* Derby, June 11 Sec, Dr Donald A Davis 38 Elizabeth St, Derby *Regular Examination* Hartford, July 9-11 Sec, Dr Creighton Barker, 160 St Ronan St New Haven

DELAWARE *Examination* Dover, July 9-11 *Endorsement* Dover, July 18 Sec Dr Joseph S McDaniel, 225 S State St Dover

DISTRICT OF COLUMBIA * *Examination* Washington, May 13-14 Deputy Director Mr Paul Foley, 1740 Massachusetts Ave, N W, Washington

FLORIDA * *Examination* Miami June 23-25 Sec, Dr Homer L Pearson 901 N W 17th St, Miami

GEORGIA *Examination and Reciprocity* August and Atlanta, June Sec, Mr Cecil L Clifton 111 State Capitol, Atlanta 3

IDAHO *Examination and Reciprocity* Boise July 8-10 Exec Sec, Mr Armand L Bird 364 Sonna Bldg Boise

ILLINOIS *Examination and Reciprocity* Chicago, June 17-21 Supt of Regis Mr Fredric B Selcke, Capitol Bldg, Springfield

INDIANA *Examination* Indianapolis, June 19 21 Exec Sec, Miss Ruth V Kirk, 538 K of P Bldg, Indianapolis

KANSAS *Examination and Endorsement* Kansas City, June 5-6 Sec Dr Lyle F Schmaus, 864 New Brotherhood Bldg, Kansas City

KENTUCKY *Examination* Louisville June 10-12 Sec, Dr Russell E Teague 620 S 6th St Louisville

LOUISIANA *Examination and Reciprocity* New Orleans June 6-8 Sec Dr Edward H Lawson, 930 Hibernia Bank Bldg, New Orleans 12

MAINE *Examination and Reciprocity* August, July 9-11 Sec, Dr Adam P Leighton 192 State St Portland

MARYLAND *Examination* Baltimore, June 18-21 Sec, Dr Lewis P Gundry, 1215 Cathedral St, Baltimore 1

MASSACHUSETTS *Examination and Endorsement* Boston, July 9-12 Sec, Dr Robert C Cochrane, 37 State House, Boston 33

MICHIGAN * *Examination* Ann Arbor and Detroit, June Sec, Dr E C Swanson 118 Stevens T Mason Bldg, West Michigan Ave, Lansing 8

MISSISSIPPI *Examination* Jackson, June 24-25 *Reciprocity* Jackson, June 26 Asst Sec, Dr R N Whitfield, Old Capitol, Jackson

MISSOURI *Examination and Reciprocity* Jefferson City, May 31-June 1 Exec Sec, Mr John A Hailey, Box 4, State Capitol Bldg Jefferson City

NEBRASKA * *Examination* Omaha, June 17-19 Director, Mr Husted K Watson, Room 1009 State Capitol Bldg, Lincoln 9

NEVADA * *Examination and Reciprocity* Reno, June 4 Sec, Dr George H Ross, 112 North Curry St Carson City

NEW HAMPSHIRE *Examination and Reciprocity* Concord, Sept 11-13 Sec., Dr John S Wheeler, 107 State House, Concord

NEW JERSEY *Examination* Trenton, June 18-21 Sec Dr Patrick H Corrigan 28 West State St, Trenton

NEW MEXICO * *Examination and Reciprocity* Santa Fe May 20-21 Sec, Dr R C Derbyshire, 227 E Palace Ave, Santa Fe

NEW YORK *Examination* Albany, Buffalo, New York, Rochester and Syracuse July 9-12 Sec, Dr Stiles D Ezell, 23 South Pearl St, Albany 7

NORTH CAROLINA *Endorsement* Asheville, May 5, and Raleigh, June 18 *Written Examination* Raleigh, June 17-20 Sec Dr Joseph J Combs Professional Bldg, Raleigh

NORTH DAKOTA *Examination* Grand Forks, July 10-13 *Reciprocity* Grand Forks, July 13 Sec Dr C J Glaspel, Grafton

OHIO *Examination and Reciprocity* Columbus, June 13 15 Sec, Dr H M Platter, 21 W Broad St, Columbus

GOVERNMENT SERVICES

AIR FORCE

Clerkships For Junior Medical Students—About 110 U S Air Force junior medical students in 57 medical schools and colleges will be afforded clinical and research training during their vacation periods this summer Clerkship programs of about eight weeks duration will be held in 18 U S A F hospitals, 2 aero medical laboratories, and the School of Aviation Medicine The purpose of the program is to provide professional experience that will be of value in the final year in medical school and during the students subsequent service as Air Force medical officers

ARMY

Personal—Col Francis E Council, M C, was placed on the retired list April 1, after having served more than 30 years on active duty His last assignment was as deputy director of the Armed Forces Institute of Pathology Colonel Council has left for Fort Worth, Texas, where, as a pathologist, he will be associated with John J Andujar, M D, of the Fort Worth Medical Laboratories

VETERANS ADMINISTRATION

Changes in Hospital Managers—Dr Thomas P Crane, manager, VA Hospital, Dearborn, Mich, became manager of the VA Hospital, San Francisco, May 5, succeeding Dr James G Donnelly, who retired April 30 Dr Earl P Brannon, manager, VA Hospital, Perry Point, Md, was transferred to the VA Hospital at Coatesville, Pa, as manager, to fill the vacancy created by the resignation of Dr Henry Luidens Replacing Dr Brannon at Perry Point will be Dr Lee G Sewall, manager of the Leech Farm Road VA Hospital in Pittsburgh To fill the vacancy created by the transfer of Dr Sewall, Dr Edward R Bennett, director, professional services, VA Center, Biloxi, Miss, will be reassigned as manager of the Pittsburgh hospital

Personal—Dr Stewart T Ginsberg, chief, psychiatry division, VA central office, Washington, D C, left May 1 to become Commissioner of Mental Health for the State of Indiana He also will be professor of psychiatry at the Indiana University School of Medicine in Indianapolis

PUBLIC HEALTH SERVICE

Poliomyelitis Vaccination Campaign—Representatives of the National Foundation for Infantile Paralysis, the American Medical Association, the Association of State and Territorial Health Officers, and the Public Health Service decided March 30 to undertake year-round campaigns to promote use of the poliomyelitis vaccine, Surgeon General Leroy E Burney announced

Consensus was that the goal of vaccinations for all persons up to the age of at least 40 should be maintained The group endorsed the recommendation that where there are limited supplies on hand special emphasis should be given first to the group under age 20 and pregnant women As supplies become available, vaccinations should then be carried out at least in persons through the age of 40 Local communities were urged to continue their planning so that they can make prompt use of the vaccine as it becomes available

The representatives of the organizations told the surgeon general that they did not believe a federally operated allocation system is necessary to achieve an equitable distribution of the vaccine The group recommended that the Public Health Service continue to collect and make available information on vaccine supplies as well as the status of community vaccination programs as a guide to communities and the manufacturers As of March 25 there were at least 3,220,000 cc, as compared with 4,765,000 cc on March 17, and 7,500,000 cc on March 10 It would appear that a considerable number of United States communities have delayed vaccination programs pending more definite assurance of supplies

The Public Health Service data will be transmitted to state health officers, the American Medical Association, the National Foundation for Infantile Paralysis, the vaccine manufacturers, and the public

In the course of the meeting, Public Health Service staff members summarized production figures to date and submitted the estimates of the manufacturers of prospective production between now and July 1 During the next three months it is estimated that between 35 and 40 million cubic centimeters will be produced

It was pointed out that, beginning last August, because of public apathy, unused vaccine began to pile up in manufacturers hands By Jan 1, it amounted to 26 million cubic centimeters By March 15, as a result of campaigns undertaken by the various groups, the backlog of 26 million had been shipped, moreover 10,500,000 cc of new supplies produced since the first of the year had also been sold Prospective production of 35 to 40 million cubic centimeters, added to the amount already made available since Jan 1, will total 75 to 80 million by July 1 This is equivalent to the total amount used during 1956 Total vaccine which will have been made available by July 1, since the beginning of the program, amounts to about 185 million cubic centimeters

There are 109 million persons up to 40 years of age in the United States The latest estimates indicate that over 56 million persons have had one or more injections, 46 million of these are children and youth under 20

Staff members of the service's Communicable Disease Center presented data collected by the Public Health Service's poliomyelitis surveillance unit on incidence These studies showed that during 1956 about three quarters of paralytic cases occurred in persons under 20 Within this group the highest rates occurred in preschool children It was agreed that special attention should be given in educational and promotional campaigns to encouraging vaccinations of the group under 5 years of age and to children in low-income families

The surgeon general asked that representatives of the groups meet with him again within the next few months to discuss detailed plans for the year-round campaign to promote use of the vaccine, particularly the third injections which will be due for millions of individuals in the fall

Survey of Indian Health Conditions—The House Appropriations Committee had asked the U S Public Health Service to determine the health needs of the American Indians, the measures necessary to bring Indian health to an acceptable level, and the estimated costs The report of this comprehensive survey of Indian health conditions, released April 14, stated that American Indians today have health problems resembling, in many respects, those of the general population a generation ago Diseases which are largely controlled among the general population still cause widespread illness and death among Indians and health services provided for them are far short of the need An adequate health program for Indians and natives of Alaska, the report said, would cost between 60 and 65 million dollars a year and 5 to 10 years would be required to bring the program to this level of operation

Health problems among the Indians that are of greatest urgency are tuberculosis, pneumonia and other respiratory diseases diarrhea and other enteric diseases, accidents, eye and ear diseases and defects, dental diseases, and mental illness Substandard and overcrowded housing and lack of sanitary facilities are major factors responsible for poor health among the Indians Water is often scarce and must be taken from contaminated sources The low educational level of many Indians on reservations is a factor More than half have family incomes of less than $1,000 a year

The report calls attention to efforts being made by the Bureau of Indian Affairs to improve Indian school facilities and attendance, to help Indians resettle in cities where employment opportunities exist, and—in cooperation with tribal groups—to improve opportunities for self-support on or near reservations

The Indian population within the continental United States is estimated to be 472,000, of whom 335,000 live in areas served by the Indian health program In addition, an estimated 35,000 natives of Alaska are also served by the program

The report points out that the Indian health program has been plagued by shortages of staff, poor and outmoded facilities, and lack of supplies and equipment Heavy demands of day-to-day medical care have tended to take precedence over needed preventive services Recommendations of the Public Health Service for an improved Indian health program include improvement and extension of medical services other than in hospitals, establishment of more field health units, expansion of preventive health services with particular attention to sanitation, control of tuberculosis, and other infectious diseases, additional preventive health services for infants and children, and additional dental and mental health services

National Library of Medicine—The 84th Congress, which created the National Library of Medicine within the U S Public Health Service and transferred to it the Armed Forces Medical Library also authorized the Board of Regents The board consists of 17 members Ten are appointed by the President from the fields of science medicine, and public affairs, and 7 are ex officio members from the federal government The chairman of the board must be elected from the appointed members At the first meeting of the board in Washington, D C, March 20, Dr Worth B Daniels, clinical professor of medicine, Georgetown University was elected chairman, Dr Champ Lyons, professor of surgery, University of Alabama Medical College, was elected vice-chairman, and Lieut Col Frank B Rogers, director of the National Library of Medicine was named secretary The board considered but deferred action on the selection of a site for the proposed new library building

In addition to Dr Daniels and Dr Lyons, the appointed members of the board are Dr Basil G Bibby, professor of dentistry University of Rochester, Dr Jean A Curran, Bingham Associates Fund, Boston, Dr Michael E De Bakey, professor of surgery, Baylor University, Dr Thomas Francis Jr, professor of epidemiology, University of Michigan, Miss Mary Louise Marshall, professor of medical bibliography, Tulane University, Dr I S Ravdin, professor of surgery, University of Pennsylvania, Dr Benjamin Spector, professor of anatomy, Tufts University, and Dr Ernest Volwiler, president, Abbott Laboratories

FOOD AND DRUG ADMINISTRATION

Symposium on Antibiotics—The fifth Annual Symposium on Antibiotics, sponsored by the Food and Drug Administration, in cooperation with the journals *Antibiotics and Chemotherapy* and *Antibiotic Medicine and Clinical Chemotherapy*, will be held Oct 2 4, 1957, at the Willard Hotel, Washington, D C Five copies of contributors abstracts of 200 words or less must be submitted to Dr Henry Welch, Food and Drug Administration, Washington 25, D C, no later than Aug 19, 1957 The abstract should explain briefly what was done in the study and the results obtained The original manuscript and one copy must be submitted by Sept 2, 1957 Manuscripts must be previously unpublished material They must be typewritten, double spaced, and on one side of 8½ by 11 in paper, with no more than six illustrations Bibliographies should conform to the style of the Quarterly Cumulative Index Medicus Generic names of drugs should be used throughout the manuscript except that, the first time the drug is mentioned, the trade name may be referred to in a footnote

DEATHS

Hume, Edward Hicks, New York City, born in hmednagar, India, May 13, 1876, Johns Hopkins University School of Medicine, Baltimore, 1901, did ostgraduate work at the University of Liverpool, England, 1901-1902, conducted research in bubonic lague in Bombay, India, for the U S Public Health ervice 1903-1905, a founder and organizer of the edical school and hospital of Yale-in-China, Changha, China, where he was senior physician at the Yale Hospital from 1906 to 1923, dean, Hunan-Yale Medial College from 1914 to 1927 and professor of medine from 1916 to 1923, when he became clinical proessor of medicine, serving until 1927, president of he Colleges of Yale-in-China at Changsha from 1923 o 1927, returned to America and became executive ice-president and trustee of the New York Postgraduate Medical School and Hospital, New York City, of which he was director, served as lecturer on Chinese medical history at his alma mater, where in 938 he delivered the second Hideyo Noguchi lecture, hen called back to China for three years by the Chiese National Health Administration to effect liaison etween the health work in the various areas in China, ecretary emeritus of the Christian Medical Council or Overseas Work in New York City, of which he ecame director in 1938, received two decorations rom the Chinese government, the Order of the Flourishing Grain, Third Class, in 1926, and the Order of the Blue Jade in 1941, trustee of Lingnan University, China, Hua Chung College, Russell Sage College in Troy, N Y, Yale-in-China Association, American Council of the Institute of Pacific Relations in New York, and a director of American Bureau for Medical Aid to China, member, board of managers, American Bible Society, fellow of the New York Academy of Medicine, member of the Chinese Medical Association and for five years chairman of its council on medical education, American Society for Tropical Medicine, New York Society for Tropical Medicine, American Association of the History of Medicine, New York Society for Medical History, Phi Beta Kappa, Psi Upsilon, and Sigma Xi, an associate member of the American Medical Association, among his honorary degrees were an M A from Yale in 1912, and LL D degrees from Jefferson Medical College, Philadelphia, in 1923, and the University of Hong Kong, China, in 1925, author of "The Chinese Way in Medicine" and Doctors Courageous", joint author of Valiant Adventurer", in 1946 was given the Norton Medical Award for his book "Doctors East, Doctors West, for nine years assistant editor of the *China Medical Journal*, died in the Gaylord Farms Sanatorium, Wallingford, Feb 9, aged 80

Dunning, Henry Sage, New Canaan, Conn, born in Scarsdale, N Y, July 7, 1881, New York University College of Dentistry, New York City, 1904, Columbia University College of Physicians and Surgeons, New York City, 1911, in 1916 one of the original founders of the School of Dental and Oral Surgery at Columbia University, where he was chairman of the organizing committee, professor of oral surgery, for many years member of the administrative board, and at the time of his death professor emeritus, served on the faculty of Columbia University College of Physicians and Surgeons, member of the Medical Society of the State of New York and the American Laryngological, Rhinological and Otological Society, an associate member of the American Medical Association, fellow of the American College of Surgeons, specialist certified by the American Board of Otolaryngology and the American Board of Plastic Surgery, during World War I served overseas with a Presbyterian Hospital unit attached to the British and later became assistant chief of the maxillary surgery section, American Expeditionary Forces, during World War II was active in fund raising to supply mobile dental equipment for the British and Australian forces, and taught oral and plastic surgery to medical and dental officers of the armed forces at the Columbia-Presbyterian Medical Center, where he was chief of the oral surgery clinic, in March 1948, on his retirement as an active professor at Columbia, was honored by medical and dental associates at a dinner at which he received many tributes and a gold wrist watch, in 1949, when a plaque was installed at the Columbia dental school, he again received special honors, in 1953, he received a distinguished service award at the 25th anniversary celebration of the center, was an attending oral surgeon at the Manhattan Eye, Ear and Throat Hospital in New York City, consultant in oral surgery at many hospitals, including the Jersey City Medical Center in Jersey City, Hackensack (N J) Hospital, and St Luke s Hospital, St Vincent's Hospital, New York Foundling Hospital, and the Roosevelt Hospital in New York City, died Feb 10, aged 75, of coronary disease

Pleadwell, Frank Lester, Capt, U S Navy, retired, Honolulu, Hawaii, born in Taunton, Mass, Aug 9, 1872, Harvard Medical School, Boston, 1896, appointed assistant surgeon in the medical corps of the Navy and entered the Naval service on Oct 24, 1896, after completing more than 33 years active service, retired from the Navy Dec 22, 1929, awarded the bronze medal for service on board the USS Nashville during the Spanish-American War, the Spanish Campaign Badge for serving in Cuba, recommended for the Navy Cross for meritorious service during World War I, and received the Order of Commander of the Order of the British Empire for services rendered during World War I, delegate of U S Navy at International congresses on Nomenclature of Diseases, Paris, and Alcoholism, London, 1909, technical adviser to American delegation at Geneva in July, 1929, delegate of U S government and chairman, American delegation, XI International Congress, History of Medicine at Zagreb, Belgrade, Sarajevo, and Dubrovnik, Yugo-

Utts, Charles William, Connellsville, Pa , Western Pennsylvania Medical College, Pittsburgh, 1905, died in the Connellsville (Pa) State Hospital Jan 19, aged 80, of cerebral hemorrhage

Vanderslice, Augustus M , Lincoln, Neb , Nebraska College of Medicine, Lincoln, 1909, died Jan 4, aged 88, of coronary occlusion

Vandiver, Howard Asberry, Reno, Nevada, Creighton University School of Medicine, Omaha, 1921, service member of the American Medical Association, veteran of World War I and II, served on the staffs of St Mary's Hospital at North Platte, Neb , and the Veterans Administration Hospital in Phoenix, Ariz , on the staff of the Veterans Administration Hospital, where he died Jan 7, aged 61, of perforation of the esophagus

Verbrycke, J Russell Jr ⊕ Washington, D C , Georgetown University School of Medicine, Washington, D C , 1906, formerly associate professor of clinical medicine at his alma mater, member of the American Gastro-Enterological Association, fellow of the American College of Physicians, for many years consultant at Garfield Memorial Hospital, died Feb 5, aged 71, *of chronic myocardosis*

Waldie, George McLeod ⊕ Ishpeming, Mich , Tufts College Medical School, Boston, 1911, member of the Industrial Medical Association, American College of Chest Physicians, and the American Trudeau Society, resigned in 1939 as medical superintendent of the Copper Country *Sanatorium in Houghton, died in St* Anthony's Hospital, St Petersburg, Fla , Dec 13, aged 66, of arteriosclerotic heart disease

Walters, George Warren, Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1899, died Jan 4, aged 80, of coronary occlusion

Weems, George Emerson, Apalachicola, Fla , Atlanta College of Physicians and Surgeons, 1904, died in the W T Edwards Tuberculosis Hospital in Tallahassee Nov 26, aged 75, of pulmonary tuberculosis

Wegner, William Godfrey ⊕ South Bend, Ind , College of Physicians and Surgeons of Chicago, School of *Medicine of the University of Illinois*, 1898, died Nov 17, aged 83, of arterioscerotic heart disease

Weintrob, Joseph Roosevelt ⊕ Atlantic City, N J , Jefferson Medical College of Philadelphia, 1937, specialist certified by the American Board of Ophthalmology, member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology, veteran of World War II, chief of eye service for Atlantic City Hospital, died in Margate City Jan 28, aged 44

Wells, William Monroe, Orlando, Fla , Meharry Medical College, Nashville, Tenn , 1914, died in Lakeland Jan 21, aged 67

White, Charles Augustus ⊕ St Louis, Medical College of Indiana, Indianapolis, 1898, retired district surgeon, Wabash Railroad, on the staffs of the Incarnate Hospital and the Missouri Baptist Hospital, where he died Jan 13, aged 91, of duodenal ulcer with hemorrhage and arteriosclerotic heart disease

Whitehead, Charles Edgar ⊕ Bozeman, Mont , John A Creighton Medical College, Omaha, 1908, veteran of World War I, on the staff of the Bozeman Deaconess Hospital, died Dec 18, aged 73, of hypertension and congestive heart failure

Whiteside, Charles Thomas ⊕ Kayford, W Va , Chicago College of Medicine and Surgery, 1915, veteran of World War I, served on the staff of the Charleston (W Va) General Hospital, died in Venice, Fla , Feb 25, aged 68, of pleural effusion

Whitley, James Roger ⊕ Winder, Ga , Emory University School of Medicine, Atlanta, 1938, interned at the Baroness Erlanger Hospital in Chattanooga, Tenn , where he served a residency, died in St Mary's Hospital, Athens, Jan 5, aged 44, of myocarditis and arteriovenous fistula

Wiegmann, William Henry, New York City, New York University Medical College, New York City, 1898, died Dec 28, aged 80, of carcinoma of the bladder

Winn, George Elisha ⊕ Defiance, Ohio, University of Nashville (Tenn) Medical Department, 1900, Ohio Medical University, Columbus, 1901, veteran of World War I, died Jan 18, aged 79, of a heart attack

Woodbridge, James Warren ⊕ Fresno, Calif , College of Physicians and Surgeons, Keokuk, Iowa, 1893, member of the Iowa State Medical Society, veteran of World War I, *formerly practiced in Emmetsburg,* Iowa, where he was president of the Palo Alto County Medical Society, died Jan 2, aged 87

FOREIGN LETTERS

CANADA

Hospital Insurance for Ontario —Up to the end of anuary, the health insurance situation in Canada had emained fairly static for several months The proposal of the federal government for cost-sharing in a univeral hospitalization or other health insurance plan deended on a favorable vote of the majority of the 10 rovinces of Canada agreeing on provincial plans aceptable to the federal government The first to agree ere British Columbia, Alberta, and Saskatchewan, hich already had some form of hospital insurance For implementation of the federal plan, however, participation of one of the two thickly populated provinces of Canada, either Ontario or Quebec, was ssential It now looks as if this condition soon may be satisfied, for the Ontario legislature in January worked out a plan that would cover hospital insurance hroughout the province Premier Frost, of Ontario, stimated that this plan would cost about 300 million dollars annually and that it could start by Jan 1, 1959, provided that the federal government was prepared o play its part The suggestions of the Ontario government are outlined in a brochure entitled Hospital Care Insurance for Ontario—The Proposal of the Ontario Government' This monograph begins with a description of the background of hospital-care insurance, stressing the significance of hospital care in health services It shows that the crippling costs of hospital care have been met in Ontario by 68% of the population who have insured themselves, particularly hrough the Blue Cross Substantial numbers of the population, however, are uninsurable The Ontario government believes that everyone should have available a method of budgeting hospital costs that can be maintained at all stages of life, regardless of age, health, or economic status Premier Frost sees the role of his government as that of meeting only absolutely essential needs Many will wish to insure themselves beyond these basic needs It is in this field that private enterprise will be allowed full scope

In the brochure, the Ontario government takes issue with the federal government on the latter's proposals Ontario intends to include mental and tuberculosis hospitalization costs, although the federal government excludes these Ontario does not agree with the unwillingness of the federal government to share administrative costs, nor does she agree to the federal cost-sharing formula Administrative details of the plan have not yet been published A three-man hospital services commission was set up in Ontario and charged with the development of a balanced and integrated system of hospital and related health facilities Presumably this commission will administer hospital insurance as and when it develops The carrier could be Blue Cross or a new government corporation Hospitals will continue to be owned by local communities and charitable organizations

The Ontario plan is designed to cover inpatient diagnostic services, standard ward-care in active treatment hospitals (but not medical practitioners' fees), care in convalescent hospitals and hospitals for the chronically ill, specific outpatient services, and, either simultaneously or later, outpatient diagnostic services Benefits will be available to all Ontario residents who have insured themselves by paying a personal premium Benefits will be available to all persons in receipt of public assistance and also to medically indigent persons It is intended that membership in the plan will ultimately be compulsory for all residents who can afford to pay This plan differs in some details from the federal proposal, but discussion has taken place between the two governments, with a view to ironing out these differences In any case the differences do not seem great enough to warrant a federal refusal to share in the plan On Feb 5, the possibility of nationwide health insurance was brought a step nearer by Newfoundland's acceptance of the federal government's plan This makes a total of 5 of the 10 Canadian provinces accepting the federal offer A sixth will probably join within the next few months, in which case the plan is virtually assured of a start

Mental Hospital Care —In 1954 the National Scientific Planning Council of the Canadian Mental Health Association started a study of mental health services in Canada, because the present design and administrative pattern of these services was believed to be out of date The Committee on Mental Health Services was set up, and its first report dealing with mental hospital care has appeared The committee points out that in the decade 1941 to 1951, the bed capacity in Canadian psychiatric services rose by about 6,000 beds, while the number of patients rose by over 10,000 Professional personnel increased three to four times, and the nursing staff became 50% larger, while per capita daily expenditure rose from 96 cents to $2 40 In this decade psychiatry may be said to have established itself in Canada, but there is still much to be done and a great need for more mental hospital beds and trained psychiatric personnel of all kinds In the last few years the situation has been reviewed by several provinces and also at local levels, but there appears to have been a more or less uniform failure to implement the recommendations contained in these surveys The present report suggests that the reasons for this have been, in part, economic Tensions between different parties interested in mental health facilities have played a part, while lack of a clear program and clear bases for recommendations have hampered development The apathetic or negative public attitude and the tendency to lose sight of mental health services in a general public health plan also retarded development

---

The items in these letters are contributed by regular correspondents in the various foreign countries

The committee concludes that overcrowding in mental hospitals must be publicized Services must develop on a regional basis in natural demographic and geographical areas, within limits of provincial administration No more large mental hospitals or additions to existing large mental hospitals should be built Future facilities must be in close proximity to medical centers and particularly to teaching centers The committee envisions regional mental hospitals of not more than 400 or 500 beds integrated with regional medical facilities in centers of population In addition to the hospital some form of community clinic will continue to play a central role in future development of community mental health programs The mental hospital must be a part of an integrated unit, including the general hospital the medical school clinics, social agencies, and private practitioners

How Hard Does the General Practitioner Work?—It would appear from figures obtained by a questionnaire in Ontario that the working hours of the Canadian general practitioner are similar to those of his counterpart in the United States The average general practitioner sees about 25 patients daily, works an 11-hour day, and spends three nights a week in his office The general practitioners who worked the hardest (11 8 hours a day) were those in towns of 5,000 to 50,000 population The general practitioners in rural areas worked a 10 5-hour day, whereas those in the big cities worked a 10 7-hour day Nearly half of the general practitioners had secretarial help, generally on a full-time basis, but 20% still relied on their wives for such work It should be noted that the secretaries or nurses worked only 6 2 hours a day on an average Nearly 60% of the practitioners still do some of their own laboratory work, including urine testing

In Defence of Nursing—Early in the winter the *Canadian Medical Association Journal* published an article, entitled "In Defence of Nursing," in which modern nursing education was severely criticized by two physicians Briefly the physicians charged that, whereas Florence Nightingale was most preoccupied with the character and personality of nurses, her present-day successors seem much more concerned with academic distinction and technical abilities Learning at the bedside has given place more and more to classroom learning, within which much basic science has been included The authors questioned whether much of the material taught in the basic sciences was found valuable by nurses later on They contended that there is only one basic science of nursing and that is simply nursing They were perturbed at the growing tendency of nursing educators to advise five-year courses, more academic work, and a decreased quantity of ward experience The physicians suggested that the time had come to analyze the educational requirements of a nurse and also her personal qualities In rebuttal of some of these allegations, the director of the School of Graduate Nurses, McGill University, states that the ideal of bedside teaching is difficult to attain because of the vast amount of work to be done in the average ward As a matter of expediency, much essential subject matter must be taught in the classroom, and limitations of time and teaching personn make some of this teaching unsatisfactory The fa that the average hospital demands so much of th students time in carrying out numerous routine job essential in the care of the sick cuts down the tim available for teaching The five-year college progra decried by the physicians has been set up to prepar properly qualified educators who need a large measur of knowledge if they are to work effectively wit others Students of nursing in hospitals should be prepared not only to take their place beside the hospita bed but also to take their place in community nursin in the broadest sense, hence there is a need for independent nursing schools, outside the framework of th hospital, in which care of patients will not conflic with education of students

Sensitivity Tests for Antibiotics—Testing microorganisms for sensitivity to antibiotics is an essentia but difficult procedure Use of the dry antibiotic disk introduced as a simple and accurate means of screening the sensitivities of micro-organisms, has bee widely accepted in hospital laboratories, but ther have been disquieting reports of gross discrepancies i results obtained with these disks Greenberg and co-workers, therefore carried out a survey of commercia antibiotic disks They first manufactured control o reference disks of their own and developed technique for extraction of the antibiotic from them for assay purposes They then obtained samples of commercia disks and assayed the latter The results showed tha the potencies of most commercial disks were not i accordance with the labeled claims Greenberg and co-workers tested 92 lots of commercial paper-type disks and found that 61 of them had less antibiotics than claimed, 9 had more, and 22 met the labeled claims There was enormous variation between results of different tests In one series, a batch of penicillin disks labeled 10 units contained only a trace of antibiotic, while another batch manufactured by a different company had over 30 units Steps are being taken under the Canadian Food and Drugs Act to insure that only properly manufactured disks are distributed in Canada Manufacturers of antibiotic disks will be required to show that, within the limits of error of the assay concerned, their disks contain the precise amount of antibiotic as labeled throughout the period recommended for its use

Artificial Heart-Lung Preparations—In describing their experiences to date with artificial heart-lung preparations, Mustard and Thomson (*Canadian Medical Association Journal*, Feb 15 1957) note the advances that have been made in caval-aortic bypass to facilitate open dry-heart surgery since the first animal survival of such surgery in 1937 They have not found human lungs efficient but have proved the clinical value of washed donor monkey lungs Monkeys, after their kidneys have been removed, are obtained from local research laboratories The lungs and hearts of four monkeys are removed en bloc A cannula is introduced into the trachea and another into the right ventricle through the pulmonary artery The web between aorta and pulmonary artery is perforated and the pulmonary artery cannula tied in place. Unwanted parts of the heart are excised. The vascular tree is flushed out with heparinized dextran in normal saline solution, with penicillin and streptomycin added. There is a hazard of pulmonary edema, thus a bank of four pairs of lungs is on hand for cardiac operations on human beings. Washed canine lungs are currently under study. The authors have performed open cardiotomy on 21 persons since 1951 using an extracorporeal circulation, with a pump and monkey lungs as oxygenators. Patients operated on included those with tetralogy of Fallot, ventricular septal defect, and atrioventricularis communis. Patients undergoing right ventriculotomy are poor surgical risks, and only 3 of the 21 patients survived. Results are still not adequate to advise the application of this method even in good-risk patients.

Micrococcic Pneumonia.—Recent publications show that micrococcic pneumonia is becoming more common in children and increasingly resistant to known therapeutic and antibiotic agent. Briggs (*Canadian Medical Association Journal*, Feb. 15, 1957) records 27 cases of primary micrococcic pneumonia. Only 5 of the children were more than 5 months old; 12 died. Presenting symptoms included cough in 16 patients, cyanosis in 8, and fever in 18; there was a history of previous infection in 10. Complications were common, occurring in 22 of the 27 patients, and included abscess, empyema, pneumothorax, pericarditis, and osteomyelitis. Fourteen of 25 patients had nasopharyngeal swabs positive for Micrococcus pyogenes var. aureus, and in all cases the pleural fluid was positive for these organisms, whereas the blood culture was positive only in one case. Examination of antibiotic sensitivities showed that only chloramphenicol and erythromycin were effective, other antibiotics being of little value. The authors believe that micrococcic pneumonia is related to initial contact of the newborn child with the Micrococcus. They found M. pyogenes var. aureus in nasal swabs of 84% of people connected with the maternity unit and in many of these subjects the pathogen was already resistant to the more common antibiotics.

Aldosterone and Hypertension.—Some interesting experiments on the production of experimental hypertension by injection of aldosterone into rats are described in the *Canadian Journal of Biochemistry and Physiology* for January. First a method was evolved for the isolation of aldosterone from commercial aqueous adrenal cortical extracts. A chloroform extract of the hormone was separated by chromatography by a method yielding 4 mcg. per milliliter of original extract. Aldosterone was injected subcutaneously into young rats at first in doses of 0.5 mcg. per 48 hours and later in doses of 1 mcg. per 24 hours. After 6 to 12 weeks a significant rise in blood pressure occurred. This continued until after about five or six months and reached a maximum averaging 75 mm. above control values. Administration of saline solution instead of drinking water had no significant effect on the result. Rats that had undergone an adrenalectomy responded in a similar way. A direct effect on the kidneys seems to be excluded by the fact that proteinuria developed in the rats only after the rise in blood pressure. These results contradict those of Gross and co-workers, who used a much larger dose of aldosterone over a shorter period and produced no rise in blood pressure. It was suggested that excesses of aldosterone above a certain level required to produce changes are without further effect. It may be that the hypertensive animals represent the experimental counterpart of human essential hypertension. This view is supported by reports that patients with essential hypertension have been found to excrete increased quantities of aldosterone.

UNITED KINGDOM

National Health Service Crisis.—What little hope there was of the medical profession's claim for increased remuneration being settled without provoking a major crisis in the National Health Service has been well-nigh obliterated by the action of the Prime Minister. Without warning or consultation with the profession, he announced that the government proposes to set up a royal commission on the remuneration of physicians. The committee is to consider the following: (1) how remuneration from all sources now received by physicians and dentists taking any part in the National Health Service compares with the remuneration received by members of other professions, by other members of the medical and dental professions, and by people engaged in occupations connected with these professions, (2) what, in the light of the foregoing, should be the proper current levels of remuneration of physicians and dentists by the National Health Service, and (3) whether and, if so, what arrangements should be made to keep that remuneration under review and what recommendations should be made. Neither the names of the members of the commission nor the date by which the commission shall start its investigations were announced. The profession's reaction to this heavy-handed and maladroit move on the part of the government has been sharp and practically unanimous. Even those who were not happy about the timing of the claim for increased remuneration believe that not only is the profession being treated with gross discourtesy but also that more fundamental issues are at stake. What is particularly galling to so many physicians is that it should be a conservative government that is treating them in this way. The inevitable reaction is that if this is how a conservative government treats the profession then there is no hope for professional freedom in the future.

A royal commission is a particularly inappropriate means for investigating a pay claim, as such commissions are notorious for the time they take to publish a report. The Prime Minister's action, therefore, appears to be simply an astute governmental step for postponing a decision for as long as possible. Presumably, because of the almost universal opposition to his action, the Prime Minister said that the appointment of this commission does not preclude some interim adjustment. This concession, offered with obvious reluctance, is still nothing more than a vague promise

The committee concludes that overcrowding in mental hospitals must be publicized Services must develop on a regional basis in natural demographic and geographical areas, within limits of provincial administration No more large mental hospitals or additions to existing large mental hospitals should be built Future facilities must be in close proximity to medical centers and particularly to teaching centers The committee envisions regional mental hospitals of not more than 400 or 500 beds integrated with regional medical facilities in centers of population In addition to the hospital, some form of community clinic will continue to play a central role in future development of community mental health programs The mental hospital must be a part of an integrated unit, including the general hospital, the medical school, clinics, social agencies, and private practitioners

How Hard Does the General Practitioner Work?—It would appear from figures obtained by a questionnaire in Ontario that the working hours of the Canadian general practitioner are similar to those of his counterpart in the United States The average general practitioner sees about 25 patients daily, works an 11-hour day, and spends three nights a week in his office The general practitioners who worked the hardest (11 8 hours a day) were those in towns of 5,000 to 50,000 population The general practitioners in rural areas worked a 10 5-hour day, whereas those in the big cities worked a 10 7-hour day Nearly half of the general practitioners had secretarial help, generally on a full-time basis, but 20% still relied on their wives for such work It should be noted that the secretaries or nurses worked only 6 2 hours a day on an average Nearly 60% of the practitioners still do some of their own laboratory work, including urine testing

In Defence of Nursing—Early in the winter the *Canadian Medical Association Journal* published an article, entitled "In Defence of Nursing,' in which modern nursing education was severely criticized by two physicians Briefly, the physicians charged that, whereas Florence Nightingale was most preoccupied with the character and personality of nurses, her present-day successors seem much more concerned with academic distinction and technical abilities Learning at the bedside has given place more and more to classroom learning, within which much basic science has been included The authors questioned whether much of the material taught in the basic sciences was found valuable by nurses later on They contended that there is only one basic science of nursing and that is simply nursing They were perturbed at the growing tendency of nursing educators to advise five-year courses, more academic work, and a decreased quantity of ward experience The physicians suggested that the time had come to analyze the educational requirements of a nurse and also her personal qualities In rebuttal of some of these allegations, the director of the School of Graduate Nurses, McGill University, states that the ideal of bedside teaching is difficult to attain because of the vast amount of work to be done in the average ward As a matter of expediency, much essential subject matter must be taught in the classroom, and limitations of time and teaching personnel make some of this teaching unsatisfactory The fact that the average hospital demands so much of the student s time in carrying out numerous routine jobs essential in the care of the sick cuts down the time available for teaching The five-year college program decried by the physicians has been set up to prepare properly qualified educators who need a large measure of knowledge if they are to work effectively with others Students of nursing in hospitals should be prepared not only to take their place beside the hospital bed but also to take their place in community nursing in the broadest sense, hence there is a need for independent nursing schools, outside the framework of the hospital, in which care of patients will not conflict with education of students

Sensitivity Tests for Antibiotics—Testing micro-organisms for sensitivity to antibiotics is an essential but difficult procedure Use of the dry antibiotic disk, introduced as a simple and accurate means of screening the sensitivities of micro-organisms, has been widely accepted in hospital laboratories, but there have been disquieting reports of gross discrepancies in results obtained with these disks Greenberg and co workers, therefore, carried out a survey of commercial antibiotic disks They first manufactured control or reference disks of their own and developed techniques for extraction of the antibiotic from them for assay purposes They then obtained samples of commercial disks and assayed the latter The results showed that the potencies of most commercial disks were not in accordance with the labeled claims Greenberg and co workers tested 92 lots of commercial paper-type disks and found that 61 of them had less antibiotics than claimed, 9 had more, and 22 met the labeled claims There was enormous variation between results of different tests In one series, a batch of penicillin disks labeled 10 units contained only a trace of antibiotic, while another batch manufactured by a different company had over 30 units Steps are being taken under the Canadian Food and Drugs Act to insure that only properly manufactured disks are distributed in Canada Manufacturers of antibiotic disks will be required to show that, within the limits of error of the assay concerned, their disks contain the precise amount of antibiotic as labeled throughout the period recommended for its use

Artificial Heart-Lung Preparations—In describing their experiences to date with artificial heart-lung preparations, Mustard and Thomson (*Canadian Medical Association Journal*, Feb 15, 1957) note the advances that have been made in caval-aortic bypass to facilitate open dry-heart surgery since the first animal survival of such surgery in 1937 They have not found human lungs efficient but have proved the clinical value of washed donor monkey lungs Monkeys, after their kidneys have been removed, are obtained from local research laboratories The lungs and hearts of four monkeys are removed en bloc A cannula is introduced into the trachea and another into the right ventricle through the pulmonary artery The web between aorta and pulmonary artery is perforated and the pulmonary artery cannula tied in place Unwanted parts of the heart are excised The vascular tree is flushed out with heparinized dextran in normal saline solution, with penicillin and streptomycin added There is a hazard of pulmonary edema, thus a bank of four pairs of lungs is on hand for cardiac operations on human beings Washed canine lungs are currently under study The authors have performed open cardiotomy on 21 persons since 1951 using an extracorporeal circulation, with a pump and monkey lungs as oxygenators Patients operated on included those with tetralogy of Fallot, ventricular septal defect, and atrioventricularis communis Patients undergoing right ventriculotomy are poor surgical risks, and only 3 of the 21 patients survived Results are still not adequate to advise the application of this method even on good-risk patients

UNITED KINGDOM

National Health Service Crisis—What little hope there was of the medical profession's claim for increased remuneration being settled without provoking a major crisis in the National Health Service has been well-nigh obliterated by the action of the Prime Minister Without warning or consultation with the profession, he announced that the government proposes to set up a royal commission on the remuneration of physicians The committee is to consider the following (1) how remuneration from all sources now received by physicians and dentists taking any part in the National Health Service compares with the remuneration received by members of other professions, by other members of the medical and dental professions, and by people engaged in occupations connected with these professions, (2) what, in the light of the foregoing, should be the proper current levels of remuneration of physicians and dentists by the National Health Service, and (3) whether and, if so, what arrangements should be made to keep that remuneration under review and what recommendations should be made Neither the names of the members of the commission nor the date by which the commission shall start its investigations were announced The profession s reaction to this heavy-handed and maladroit move on the part of the government has been sharp and practically unanimous Even those who were not happy about the timing of the claim for increased remuneration believe that not only is the profession being treated with gross discourtesy but also that more fundamental issues are at stake What is particularly galling to so many physicians is that it should be a conservative government that is treating them in this way The inevitable reaction is that if this is how a conservative government treats the profession then there is no hope for professional freedom in the future

A royal commission is a particularly inappropriate means for investigating a pay claim, as such commissions are notorious for the time they take to publish a report The Prime Minister s action, therefore, appears to be simply an astute governmental step for postponing a decision for as long as possible Presumably, because of the almost universal opposition to his action, the Prime Minister said that the appointment of this commission does not preclude some interim adjustment This concession, offered with obvious reluctance, is still nothing more than a vague promise

One of the complications is that the new Minister of Health appears to be almost as completely in the dark as to the Prime Minister's intentions as the press and the medical profession The result is that the representatives of the British Medical Association are becoming involved in a game of shuttlecock between the Prime Minister's office and the Ministry of Health The attitude of the association is still that the claim for increased remuneration should be settled by consultation Should such consultation fail, they have agreed to submit the matter to arbitration There seems little, if any, hope now of the government agreeing to this procedure, and at its meeting on Feb 28 the Council of the Association adopted the following resolution

The Council fully supports the decision to convene a special conference of representatives of local medical committees and to recommend to that conference that, unless the Government agrees to an immediate and *satisfactory settlement of the profession's claim or to* arbitration, general practitioners throughout the country will be advised to send in their resignations from the service " This special conference is not likely to be held before April A decision to call on all general practitioners to resign from the service would require three months notice on the part of practitioners, so that no decisive action can be taken until well after midsummer

On this question of mass resignation, the profession is by no means united The views of those who believe that such conduct is scarcely in keeping with professional standards of conduct are well epitomized in an editorial in the *Lancet* which states

> In our view this proposal is wrong we think that even if it were 100% successful such action would still do great harm to the profession—more harm than could be done by any Government In offering this opinion we do not mean that doctors need remain in a service in which they lose confidence we think that those who, now or later, want to leave the N H S should certainly do so and we agree that if any substantial exodus were in prospect the professional organizations would need to do all they could to help both their members and the public to overcome the difficulties thus arising But a genuine decision by individual doctors to return to private practice would be quite different from a withdrawal, or the threat of a withdrawal organized for political ends This we regard as an alien procedure, out of keeping with the character of any profession, and especially that of medicine

Desperate Remedy —The *Times* described as a desperate remedy the decision of the General Medical Services Committee of the British Medical Association to arrange for the progressive withdrawal of general practitioners from the National Health Service This decision has been taken after a further meeting between the Prime Minister and the two joint-chairmen of the profession s negotiating committee, at which the Prime Minister talked airily about inflation and the present economic state of the country and, on awkward questions being asked, took refuge behind the Royal Commission, which is proving just as effective a smoke screen as was expected The members of the Royal Commission are notable for their admirable qualities as citizens, but their qualifications for this particular task are difficult to establish A special conference of local medical committees, to be held on April 30 *will have before it the recommendation* from the General Medical Services Committee of the British Medical Association that, as there has been neither a satisfactory settlement of the profession's claim nor the submission of that claim to arbitration, (1) the resignation of all National Health Service general practitioners will be collected forthwith and held, and (2) the committee's plan for a progressive withdrawal of general practitioners from the National Health Service will be put into effect until such time as a satisfactory settlement is achieved or the dispute is referred to arbitration

The association will take steps to obtain the resignations of all National Health Service general practitioners These resignations will be collected, held, and put into effect initially in a number of selected areas The number of such areas will be progressively increased if the need arises Practitioners in the areas selected will be asked to notify executive councils on July 2 *of their intention to withdraw from the medical list* as of Oct 2 They will be asked not to withdraw from the obstetric list This means that after Oct 2 with the exception of maternity service, general practice under the National Health Service will cease in these areas

During October, former National Health Service patients will be treated privately, but no private fees will be asked for them The public will be informed that physicians in these areas are anxious to give the government one last chance to honor the promises made to the profession when they entered the National Health Service in 1948, and that they are doing everything possible to avoid a position in which their patients suffer financially Nevertheless, if the government still declines to agree to a satisfactory settlement or to arbitration it will be necessary, after November, for general practitioners in those areas to charge their patients a standard token fee, which it is recommended should be 70 cents for office consultation and $1 for a house call Patients are to be given receipts for these fees and advised to take them to the nearest national insurance office in order that the government may have an opportunity of refunding the sums involved Physicians will have discretion to waive or modify these fees in special cases, such as in the case of old age pensioners Neither do these arrangements preclude the introduction of contributory schemes for medical treatment in areas where such arrangements may be practicable If a settlement is not reached within a reasonable time, practitioners will be compelled to make full-scale charges for their services

As general practitioners who resign from the service cannot issue prescriptions on the official prescription form, they will be advised to write them on private forms It will be explained to the public that, although the government has broken its contract with the physicians, it still has an obligation to the patient It is, therefore, for the government to decide whether it will refuse to accept prescriptions issued in this way No national insurance certificates will be issued General practitioners will issue their own private certificate forms Practitioners in the selected areas who resign *from the service will be given financial support* and their remuneration will be supplemented from the defense trusts in accordance with the amount of their last quarterly checks from the National Health Service executive council, less the total amounts received from private practice and maternity fees Physicians in all areas are being asked to agree to an additional levy of about 4 cents per patient per quarter This will be paid into a special account, and any balance not used will be repaid when the dispute is settled

Physicians employed by local authorities and hospitals will refrain from any steps which might embarrass their general practitioner colleagues Industrial medical officers will be asked to give similar moral support At the moment of writing it is difficult to assess what the reactions of general practitioners will be to this move on the part of the British Medical Association The more responsible sections of the press, as represented by the *Times* and the *Economist,* are more critical of the attitude of the government than of that of the British Medical Association The fact that the Prime Minister simultaneously is calling for arbitration in settlement of the outstanding disputes in the shipbuilding and engineering industries, but refuses it to the physicians, has caused a flood of sympathy for the doctors That the drastic decision to try and arrange a mass withdrawal from the National Health Service is by no means a unanimous decision is indicated by the fact that the North Northumberland branch of the association has decided by a majority vote against withdrawing from the service, on the grounds that it would be against the interests of the country to take such action at present There is a growing consensus that this will probably be the feeling of most general practitioners who, much as they dislike the disgraceful manner in which they have been treated by the government, are still old fashioned enough to believe that anything remotely resembling strike action is not worthy of the profession of medicine

Fatigue in Mothers —In his annual report for 1956, Dr John Maddison, the health officer for Twickenham, says that in the infant welfare clinics young mothers seem to complain more of fatigue than their mothers used to do These women are those with one or two young children They usually come from good homes where living standards are high It is suggested that the struggle for the maintenance of high standards of health and well-being, the possession of a good home and furniture, the keeping up of appearances with the neighbors, the maintenance of a high standard of infant and child welfare, and the pressure on all sides from the welfare services and women's magazines may exhaust mothers too much It is further suggested that our striving for excellence should not be so strong and enthusiastic as to be inimical to the welfare of those for whom it is intended

Glutethimide in Obstetrics —Abbas (*Brit M J* 1 563, 1957) reports giving 250 mg of glutethimide to each of 100 women between the ages of 16 and 43 years early in the first stage of labor when it was certain that labor was definitely occurring and that uterine contractions were causing some distress Nine of the 100 patients received more than one dose A control group of 100 women with about the same age distribution and in the same stage of labor were each given 2 Gm of chloral hydrate The patients were questioned and examined every two hours and their subjective (pain) and objective (restlessness or relaxation) reactions evaluated Glutethimide was found to be an effective sedative and showed less evidence of gastric irritation than did chloral hydrate It greatly reduced the requirements of meperidine hydrochloride subsequently required for analgesia and additional sedation, the difference between the amounts needed after glutethimide and chloral hydrate being statistically significant It alleviated apprehension, thereby encouraging relaxation and cooperation, and produced no evidence of any maternal or fetal hazard The average duration of all stages of labor in primiparas and multiparas was slightly less than that after chloral hydrate had been given

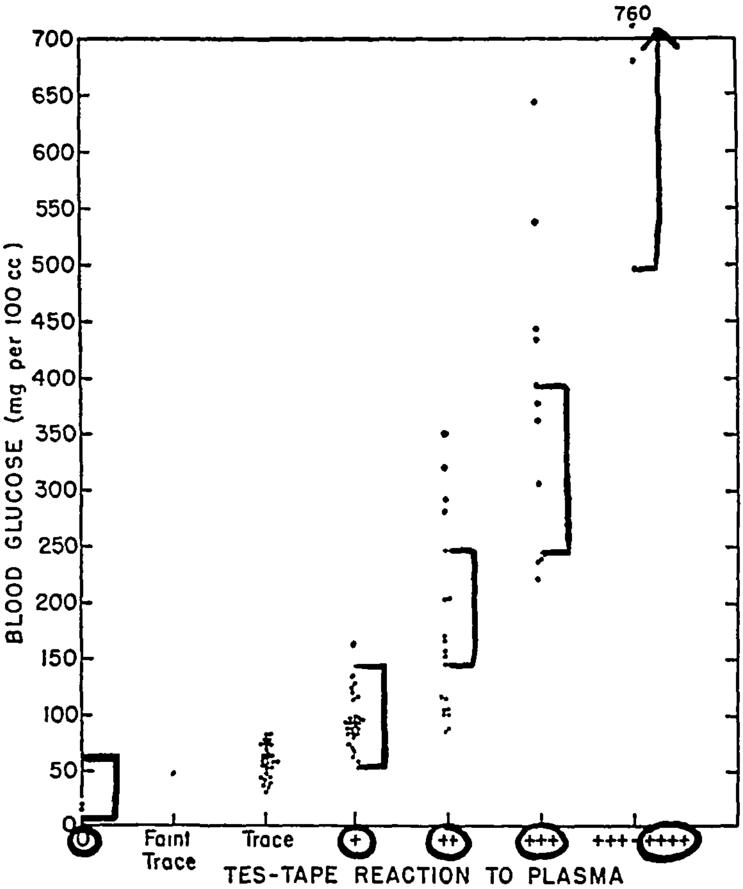
Dried Smallpox Vaccine —The fact that glycerinated smallpox vaccine deteriorates rapidly at room temperature has always been a major difficulty in hot climates in the absence of adequate refrigeration A stable, dry preparation could be stored and would be available in large quantities, should an epidemic make mass vaccination desirable Tests have been made by Cross and co-workers (*Lancet* 1 464, 1957) on dried smallpox vaccine stored at 37 C and 45 C for up to two years The vaccine consists of a suspension of vaccinia virus, purified by differential centrifugation and treated with phenol, in a solution of 5% peptone in distilled water The suspension is then lyophilized and sealed under vacuum in phials of neutral glass The vaccine, stored under the conditions mentioned, still produced 100% of successful vaccinations in Air Force personnel and showed only a slight decrease in potency by laboratory titration It should now be possible for every country to have dried smallpox vaccine which will withstand many months' or even years' exposure to tropical temperatures and which will last more or less indefinitely in an ordinary refrigerator

Nerve Damage from Thiopental —A Scottish jury rejected a patient's claim for damages against a physician for alleged negligence in giving an anesthetic The patient stated that the physician, when giving her an intravenous injection of thiopental sodium just before an operation, allowed the needle to penetrate the left median nerve, as a result of which the nerve was damaged As a consequence the patient said that she had suffered great pain in her left arm and hand and that she had some difficulty in abducting the arm In addition, it was claimed that sensation in the areas of the hand supplied by the median nerve was defective In defense it was stated that there was no evidence that the median nerve had been penetrated by the needle It was admitted, in view of the injuries of the patient, that some penetration of the nerve may have occurred, but it was contended that this was not due to negligence on the part of the physician Two expert witnesses stated that any piercing of the median nerve could have been due to involuntary muscular movements within the arm, which the physician could not have anticipated

CORRESPONDENCE

ESTIMATION OF BLOOD GLUCOSE CONCENTRATION WITH ORDINARY TES-TAPE

To the Editor —We were interested in the article by Dr Holbrooke S Seltzer in the Nov 24, 1956, issue of THE JOURNAL, page 1234 The disadvantage of his method is that it requires the separation of plasma (or serum) from the patient's blood obtained by venipuncture, this may be inconvenient for patient and doctor We have found the use of capillary blood equally satisfactory About 0 5 ml of blood can easily be collected from an ear or finger prick into a small tube (plain oxalate or heparin) After about 20 minutes enough plasma or serum will have separated to do the test as described by dipping the tape We found it usually possible to make the readings shown below



Correlation of blood glucose level with Tes-Tape reaction to undiluted plasma Brackets and circled readings indicate Baron-Oakley reading ranges

Tes-Tape Determination with Use of Capillary Blood

Tes Tape Reading	Blood Sugar (True Sugar Mg /100 Ml)
0	less than about 60
+ (1/10%)	about 60 150
++ (1/4%)	about 150 250
+++ (1/2%)	about 250 400
progressing to ++++ (2%)	500 and above

The results were absolutely reliable at either end of the scale

London, W C 1, England

The above letter was referred for comment to Dr Seltzer, who replied as follows —ED

To the Editor —The procedure of Drs Baron and Oakley is an adaptation of the original Tes-Tape method, which reduces still more the materials required to run the test and thereby enhances its convenience In general the reading ranges agree with those I found on undiluted plasma, as shown in figure 2 in my paper in THE JOURNAL, Nov 24, 1956 That figure is reproduced here with the addition of brackets to represent Baron's reading ranges There is one important difference between his readings and mine He gets no color reaction at all below 60 mg per 100 ml, whereas if we should find none at all we would rush to give glucose intravenously, since we consistently get faint trace" or "trace" shades of green in the blood glucose range of 20 to 60 mg per 100 ml It is very easy to pick up these gradations, since there is quite a gap in color reaction between the no-change of a "0 reaction and the full pastel green of a 1-plus" I do not known how to explain the discrepancy between our respective figures, since plasma and serum glucose values are essentially the same

Another point deserves comment When matching the convenience of capillary blood procurement against venipuncture plus centrifugation, one must keep in mind the clinical situation in which one is employing the test Our usual situation is in the emergency room or on the diabetic ward, where we want to know the approximate glucose level within five minutes and where venipuncture equipment and a centrifuge are available In talking about the method to various groups I have pointed out that a practitioner making a house call, with no centrifuge at hand, could draw venous blood and let it clot while completing his examination, then test the serum In summary, I think their procedure is a useful modification of the original Tes-Tape method However, I also think that a much more accurate reading of glucose values below 60 mg per 100 ml is 0 to trace" instead of straight "0"

POLIOMYELITIS VACCINE AND RECURRENT HERPES SIMPLEX

To the Editor —Smallpox vaccination has long been used with sporadic success in the treatment of recurrent cases of herpes simplex The following observations on two patients who came in contact with poliomyelitis viruses may be of some value in the future treatment of recurrent herpes simplex

A 25-year-old man gave a history of repeated attacks of herpes simplex on the lower lip since childhood These episodes would occur about every three months, but the patient had never previously seen a physician for any form of treatment During the first seven months of 1956, he was employed in the department of virology of Temple University Medical Center as a laboratory technician During the course of his occupation, he would use pipets in transferring tissue cultures containing the HeLa cell which was impregnated with all three types of poliomyelitis virus On many occasions this transfer would result in the accidental ingestion and swallowing of the liquid cultures The patient had his last episode of herpes simplex one month prior to his employment Since his accidental ingestions of the poliomyelitis viruses, he has had no recurrent episodes of his fever blisters The second patient was a 20 year-old man with a history of recurrent herpes simplex since childhood, it occurred six or seven times each year at the termination of a common cold Two standard-dose injections of poliomyelitis vaccine were given to the patient during the summer of 1956, and to this date there has been no recurrence of the fever blisters

These observations suggest that poliomyelitis vaccine, like smallpox vaccine, may prevent recurrent episodes of herpes simplex

RADIOTHERAPY DOSAGE

To the Editor —The article "Combination Therapy of Retinoblastoma with Triethylene Melamine and Radiotherapy," by George A Hyman and Algernon B Reese, in The Journal, Dec 8, 1956, page 1368, is a significant contribution to the literature on this rare tumor Few institutions could assemble 50 children with retinoblastoma for report to the medical world The work reported once again showed an important relationship between chemotherapy and radiotherapy

Those of us who see only rarely a patient with retinoblastoma will refer to the results in this large series of patients In using the article as a reference, there are striking limitations to the description of the radiation therapy To describe radiotherapy dosage as "5,600 to 8,000 r in air to the tumor or '2,400 r in air to the tumor is both inaccurate and insufficient for those readers who would like to duplicate the technique Of invaluable aid to the reader of this article would be a definition of the terminology 'r in air to the tumor" It would be of still more value for the reader to know the physical factors of the radiation employed

Norman Simon, M D
945 Fifth Ave
New York 21

The above letter was referred to one of the authors of the article, who requested an associate to reply —Ed

To the Editor —Dr Algernon B Reese has referred to me, as one of the radiotherapists now participating in a project to evaluate the combined effect of triethylene melamine and radiotherapy in the treatment of retinoblastoma, the letter requesting greater detail concerning the technique of radiation employed in this study

The following method is applicable only to those patients with bilateral tumors who have had one eye removed, and where there is no evidence of tumor invasion of the optic nerve of the enucleated eye On the fifth to seventh day after enucleation, external irradiation to the remaining eye is instituted A contour of the head is obtained and a plan is drawn up with reference to the estimated area of interest, i e, the entire globe posterior to the lens to include at least 1 cm of the optic nerve Two portals are used The nasal portal measures 2 0-2 5 cm in diameter and is placed in the enucleated orbit against the bridge of the nose and angled so that the beam of radiation will pass posterior to the lens of the eye under treatment This angle usually approximates 24 to 30 degrees A localization film is obtained showing that the exit point of the beam is posterior to the outer canthus The lateral portal may be a 2 5-cm circle but preferably is a rectangle 3 by 4 cm, with the long axis oriented in the cephalad-caudad direction The anterior margin of this port is at the lateral limbus, again to ensure passage of the beam posterior to the lens

We plan on delivering a tumor dose of 3,500 r to the entire retina posterior to the lens in a three-week period The patients are treated daily to each portal, the daily air dose being based on the desired daily tumor dose The total air dose to each portal varies depending upon the measurements obtained for the individual case and is usually 2,400 r to 2,800 r The factors are 220 kv, 15 ma, 50 cm target-skin distance, 1 0 mm Cu half-value layer

If it is desired to treat both eyes, an enucleation not having been performed, the nasal portal cannot be used The tumor dose of 3,500 r in three weeks is then achieved by the application of bilateral lateral portals with resultant higher air and skin doses because of the greater separation between the ports

The article by Martin and Reese published in the *Archives of Ophthalmology* (33 429-439 [June] 1945) includes diagrams showing the positioning of the patient and the application of the portals as described above

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Clinical Significance of Hyperaminoaciduria B Pépin Presse med 64 2091-2094 (Dec 15) 1956 (In French) [Paris]

Hyperaminoaciduria may be due to any 1 of 3 mechanisms 1 It may represent an overflow from an excess of amino acids in the blood, as in the hyperaminoaciduria and hyperaminoacidemia of severe liver deficiency Any significant protein catabolism, in so far as it increases aminoacidemia, may also lead to hyperaminoaciduria, as in cachexia, generalized cancers, extensive burns, hyperthyroidism, or adrenal corticotherapy 2 An obvious renal defect may, by leading to defective tubular absorption, be responsible for an excess of amino acids in the urine even though the amino acid blood level is normal This combination may be seen in certain forms of nephritis and pyelonephritis and in visceral manifestations of lupus erythematosus 3 Hyperaminoaciduria may be primary, that is, it may appear in patients whose amino acid blood level is normal and who have no demonstrable renal lesions This type of aminoaciduria, which is the most interesting, is found in cystinuria, in the Toni-Debre-Fanconi syndrome, in hepatolenticular degeneration, and in alkaptonuria and phenylpyruvic oligophrenia

The Toni-Debré-Fanconi syndrome is a heredofamilial condition characterized by an innate error of metabolism believed by most authors to be the result of a congenital defect in the renal tubular epithelium that leads to an increased urinary excretion of amino acids, peptides, glucose, and inorganic phosphorus The symptoms can be explained in the light of the disturbed tubular reabsorption Thus, the urinary loss of phosphorus and amino acids is responsible for the bone disease, glycosuria accounts for the loss of weight and frequent acidosis and explains why some of the patients present findings suggesting hyperinsulinism, and finally the chronic loss of amino acids seems to be the essential cause of the cirrhosis of the liver that is found in some patients and that, therefore, may be regarded as a nutritional cirrhosis

Hepatolenticular degeneration is a heredofamilial condition in which the 2 essential elements are hyperaminoaciduria and a disturbance in copper metabolism Opinions differ as to which of these 2 elements is the primary and fundamental disturbance in patients with hepatolenticular degeneration Another heredofamilial disease characterized by a disturbance in the urinary excretion of amino acids is cystinuria, in which the amino acid metabolism and aminoacidemia are normal but there is an excessive excretion of cystine, lysine, arginine, and ornithine The specific hyperaminoaciduria of cystinuria is explained by a congenital disturbance in the reabsorption of these amino acids Cystinuria is accompanied by a tendency toward lithiasis, but it is otherwise compatible with health Alkaptonuria and phenylpyruvic oligophrenia are linked to a disturbance in the metabolism of the aromatic amino acids, phenylalanine and tyrosine

Hepatic hyperaminoaciduria is the result of an amino acid overflow into the blood, which in turn is caused by a failure of deamination in the liver Severe hyperaminoaciduria involving significantly increased excretion of all the amino acids and especially a massive cystinuria is found essentially in the major forms of hepatic insufficiency (acute yellow atrophy, severe viral hepatitis, and decompensated cirrhosis), but, even in the milder forms of liver disease, a slight or moderate increase in aminoacidemia is reflected in an increased aminoaciduria Secondary hyperaminoaciduria has also been found in various forms of intoxication, in progressive muscular dystrophies, and in syndromes characterized by hypercorticalism

Myocardial Infarction in a Military Population P G Keil and L V McVay Jr U S Armed Forces M J 8 166-172 (Feb) 1957 [Washington, D C]

In the Army and Air Force, an electrocardiogram is required as a part of the annual physical examination of officers 40 years of age and over The authors were surprised at the number of men whose initial tracings showed evidence of previous infarction The medical histories of these men dated the attack in about half of the cases This observation provoked an investigation of myocardial infarction in a military population Being particularly interested in advanced coronary artery disease in younger persons and in the retainability of military personnel in the service after infarction, the authors reviewed the clinical records of 107 patients hospitalized with myocardial infarction in a U S Air Force hospital during the 5-year period terminating Dec 31, 1955 Eighty-seven of these were members of the military service on active duty The remainder were retired personnel or dependents of active-duty personnel Thirty-eight infarctions occurred in patients below the age of 40 Most of the 107 infarctions occurred during the summer months, while the patients were sleeping or resting They usually occurred without a history of angina in persons who were normotensive but inclined to be obese and who smoked heavily, drank moderately, had a sedentary job, and had a family history of cardiovascular disease Thirteen of the 87 active duty

The place of publication of the periodicals appears in brackets preceding each abstract

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals Requests for periodicals should be addressed Library American Medical Association Periodical files cover 1948 to date only and no photoduplication services are available No charge is made to members, but the fee for others is 15 cents in stamps for each item Only three periodicals may be borrowed at one time, and they must not be kept longer than five days Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them military personnel died as a result of infarction, 24 returned to duty, and 50 were retired with an average disability rating of 80% The authors believe that military personnel suffering relatively mild myocardial infarction, without objective or subjective sequelae, should be returned to duty

The Significance of Nonbacterial Thrombotic Endocarditis An Autopsy and Clinical Study of 78 Cases R A MacDonald and S L Robbins Ann Int Med 46 255 273 (Feb) 1957 [Lancaster, Pa]

The subject of nonbacterial thrombotic endocarditis has been confused by the use of different terms Among the names that do not denote the true nature of the condition are terminal endocarditis, marantic endocarditis, endocarditis simplex, and degenerative verrucal endocardiosis It has been repeatedly stated that nonbacterial thrombotic endocarditis is only an insignificant finding at autopsy The chief purpose of this report is to show that nonbacterial thrombotic endocarditis has clinical as well as pathological significance Clinical and autopsy studies were made on 78 patients with this disease In 11 emboli were found that were considered to have arisen from valvular vegetations and to have caused or contributed to the patient's death The vegetations were believed to result from the thrombi formed from blood within the cardiac chambers on nonspecific areas of focal fibrocollagenous degeneration of valves Embolization is considered to result from a portion of adherent thrombus breaking off into the circulation The most commonly associated diseases in this series were cancer (36%), heart failure (30%), and vascular thrombosis (27%) The possibility that the endocardial vegetations of this condition represented sterilized vegetations of bacterial endocarditis in patients given antibiotics before death was investigated and did not prove to be the case It is important to differentiate nonbacterial thrombotic endocarditis from bacterial and rheumatic endocarditis showing some degree of activity and from atypical verrucous endocarditis of Libman-Sacks Generally speaking, this presents no difficulty The main feature is the lack of cellular reaction in the involved valve in nonbacterial thrombotic endocarditis in contrast to that in the other types The chief value of clinical recognition of nonbacterial endocarditis is in differentiating embolic cerebral vascular disease from hemorrhage and thrombosis and in directing attention to associated and, perhaps, causative conditions

The Valsalva Maneuver as a Test of Cardiac Function Pathologic Physiology and Clinical Significance R Gorlin, J H Knowles and F Storey Am J Med 22 197-212 (Feb) 1957 [New York]

In 7 normal persons and in 71 patients with various forms of heart and lung disease, forced expiration from the inspiratory midposition was performed against a pressure of 40 mm Hg and the breath held for 12 seconds The maneuver was done with the patient in the recumbent position and then with the patient on the tilt table with the head or the legs elevated 30 degrees Both directly recorded and auscultated blood pressure levels were measured in the 78 persons Other tests of circulatory and pulmonary function were performed as indicated, including cardiac catheterization in 42 persons The clinical and physiological results were correlated A normal response to the Valsalva maneuver, with an initial rise of the systemic blood pressure followed by a fall in mean and pulse pressures, with an overshoot on cessation of the maneuver, was observed in the normal persons, in pregnant women, and in cardiac patients without heart failure or vascular stenosis

An abnormal response, with an initial rise of the systemic systolic and pulse pressures, which remained elevated, and with an overshoot rarely occurring on cessation of the maneuver, was observed in 23 patients with left or right ventricular failure or tight aortic or mitral stenosis (calculated or measured valve area equal to 1 sq cm or less) There was good correlation with abnormalities in other tests of cardiac function, including elevated pulmonary capillary wedge and/or right atrial pressures Twenty-six patients showed an intermediate response, in these, a change from a normal to an abnormal response occurred with change from the head-up position to the horizontal position or to that with the legs elevated, or the response was inconstant in degree and frequency These cardiac patients had either mild left ventricular failure, mild to moderately severe mitral stenosis (calculated or measured valve area from 0 8 to 1 5 sq cm), or tight aortic stenosis, there was 1 patient with chronic cor pulmonale Correlations with findings on tests of cardiac function other than that of elevated pulmonary wedge pressure were not striking

The difference between the normal and the abnormal response to the Valsalva maneuver was believed to depend on a flattened ventricular-function curve or a flattened valvular pressure-flow curve The simplicity and reliability of the Valsalva maneuver as a clinical test using an ordinary blood pressure cuff is emphasized Its greatest clinical value lies in the fact that, in the absence of severe right ventricular failure, it can detect early left ventricular failure, tight mitral stenosis, or tight aortic stenosis

The Clinical Evaluation of Patients with Goiter M P Kelsey Mississippi Doctor 34 231-235 (Feb) 1957 [Booneville, Miss]

To learn more about the differential diagnosis of the various types of enlargements of the thyroid, the records of 323 patients with goiters were reviewed These patients had been admitted to the University of Texas hospitals from 1944 to 1955, and none of them had had previous thyroid surgery They represent a selected group, many being admitted only for evaluation by radioiodine or serum protein-bound iodine determinations, and others were referred because cancer was suspected either in the thyroid or in some other site A table in which the initial diagnosis is compared with the final diagnosis shows that it is difficult to ascertain whether a goiter is diffuse or nodular or even whether there is any thyroid enlargement Regarding the history, it is pointed out that weight loss and nervousness are not always present in hyperthyroidism, but intolerance for heat and good appetite are almost universally present Auricular fibrillation, intractable diarrhea, muscular weakness, and diplopia may be the first indications of hyperthyroidism In the physical examination, the neck should be exposed to an indirect light that produces light shadows and the patient's chin should be elevated Since the thyroid is attached to the trachea, swallowing causes the thyroid to move, whereas other structures usually remain immobile

Structures mistaken for goiters included supraclavicular fat pads, bulky sternomastoid muscles, and metastatic nodules Palpation is performed while the patient flexes the head slightly forward to relax the sternomastoid muscles During palpation the examiner should note the size and consistency of the thyroid, whether there are nodules, substernal extension or fixation to surrounding structures Exaggeration of normal lobulations may be erroneously diagnosed as nodular goiter This is particularly true in diffuse toxic goiter and in chronic thyroiditis Sixteen of 35 cases with chronic thyroiditis were diagnosed correctly as were 103 of 111 cases of hyperthyroidism Eighteen patients with metastasis from thyroid cancer had no papable goiter In twenty-six of 68 patients with cancer of the thyroid, the disease was diagnosed correctly Although there were clinical features suggestive of cancer in these 26 patients, in 148 patients with nodular goiter there were no physical signs of cancer In these patients surgical exploration revealed 24 additional carcinomas (an incidence of 16%)

Tuberculosis Among University Students A 35 Year xperience J A Myers, R E Boynton and H S iehl Ann Int Med 46 201-217 (Feb) 1957 [Lancaster, Pa]

A clinic for diagnosis and treatment of diseases of the chest was established at the University of Minnesota Student's Health Service in 1920 In an enrollment of 155,021, there were 7,530 students and faculty members who were examined for chest conditions Although many nontuberculous conditions were diagnosed and treated, tuberculosis presented the chief problem The diagnosis of pulmonary tuberculosis was made in 1,055 persons, 155 had tuberculous pleurisy with effusion, and 61 had extrathoracic tuberculous lesions Diagnostic procedures included physical examination, inspection of x-ray film, bacteriological examination of the sputum, gastric washings, thoracotomy, and pulmonary biopsy

In the schools of nursing and medicine tuberculosis was most serious and constituted a natural experiment from which information was gained concerning the evolution of tuberculosis in adults It was found that first infections in adults behave like those in children The tuberculin test showed the presence of primary tuberculosis earlier than did any other examination Only persons who reacted to the tuberculin test later developed clinical disease Periodic examinations of persons who reacted to the test revealed clinical lesions when infection was minimal and in precontagious stages The tuberculin test has been routinely administered to all students entering the university since 1928 The incidence of persons who reacted to tuberculin increased in 1946, due in part to the return of war veterans from parts of the world where tuberculosis is still rife Although the incidence again decreased, it has fluctuated, probably because of those returning from the Korean war and because of the sizable number of students from other countries on the campus While many students have been exposed to tubercle bacilli in military service, those who became infected presented problems no different from those observed among the students who became infected in childhood Roentgenologic examination of the chests of those who reacted to tuberculin became routine in 1931 Clear roentgenograms of the chest never proved absence of tuberculosis To cast shadows, lesions must have sufficient consistency to obstruct x-rays These facts were established at autopsy and from resected pulmonary units Treatment ranged from bed rest and pulmonary collapse to antituberculous drugs and resection Primary pulmonary tuberculous infiltrates resolved regardless of treatment

Antituberculous drugs were given to a few patients in whom the tuberculin reaction became positive After 1 year of treatment, reversion to nonreaction resulted in 2 patients Preventive measures consisted in managing tuberculosis as a contagious disease Since a mild or severe attack does not result in dependable immunity no attempt was made to produce immunity artificially Since the early 1930s, rigid contagious disease technique has been employed in the care of tuberculous patients in the university hospital Tuberculosis was a serious problem among university personnel until 1938, when the Board of Regents passed a ruling requiring examination of nonacademic employees, and, in 1941, of academic employees The described tuberculosis control program has had phenomenal results Students no longer die from tuberculosis, and the morbidity rate has been reduced to a small number In the classes of from 1919 to 1932 in the school of medicine, 11 died and 92 had demonstrable tuberculous lesions, while only one in the past 14 years has presented a lesion large enough to cast a shadow

Etiology of Duodenal Ulcer I Relation of Specific Psychological Characteristics to Rate of Gastric Secretion (Serum Pepsinogen) H Weiner, M Thaler, M F Reiser and I A Mirsky Psychosom Med 19 1-10 (Jan -Feb) 1957 [New York]

The serum pepsinogen level was determined in each of 2,073 Army inductees Sixty-three with values in the upper 15% and 57 with values in the lower 9% of the blood-pepsinogen distribution were selected for special study Each of these was given the Rorschach, Blacky, Draw-A-Person, Cornell Medical Index, and Saslow tests and a complete upper gastrointestinal roentgenologic examination before being sent to basic training One hundred seven subjects were reexamined between the 8th and 16th week of basic training The 1st roentgenologic examination revealed healed duodenal ulcers in 3 subjects and an active ulcer in 1 The 2nd roentgenologic examination revealed active duodenal ulcers in 5 additional men All 9 subjects with peptic ulcer were in the upper 15% of the blood-pepsinogen distribution, 8 of them being in the upper 5% Evaluation of the psychological data revealed that subjects with peptic ulcer displayed evidence of major unresolved and persistent conflicts about dependency and oral gratification Classification of the selected test population into 2 groups on the basis of criteria derived from the psychological tests was found to correlate (85%) with the 2 groups (hyperpepsinogen and hypopepsinogen secretors) derived from the physiological tests The study indicates that neither a high rate of gastric secretion nor a specific psychodynamic constellation is independently responsible for development of peptic ulcer Together however, these 2 parameters constitute the essential determinants in the precipitation of peptic ulcer

Present State of Knowledge Concerning Effects of the Sulfonylurea Compounds in Diabetes Mellitus Report of the Committee on Summarization of the Conference H T Ricketts, F D W Lukens and M E Krahl Diabetes 6 91-92 (Jan -Feb) 1957 [New York]

The committee reporting found no convincing evidence that the sulfonylurea compounds increase utilization of glucose by peripheral tissues Studies of the effects of these substances on liver glycogen levels have given conflicting results, possibly because of differences in experimental conditions There is evidence that the sulfonylurea compounds inhibit the output of glucose from the intact liver, especially that derived from fructose and galactose and possibly that resulting from stimulation by glucagon and epinephrine On the other hand, in in vitro experiments with liver slices from normal fasted and fed rats, addition of these compounds to the medium did not affect glycogenolysis or glucose output The ordinarily glycogenolytic effect of glucagon and epinephrine in such slices appears to be inhibited by the drugs Prolonged medication of normal rats has been followed by a reduction in the glucose-6-phosphatase level of the liver but this effect was in no instance correlated temporally with the hypoglycemia It was not observed in the livers of alloxan diabetic rats Destruction of insulin either in the whole animal or in isolated liver preparations was not significantly reduced by concentrations of the drugs sufficient to cause hypoglycemia

The great preponderance of evidence indicates that these sulfonylurea compounds have no effect on the alpha cells of the pancreas While toxic dosages have resulted in a distinct decrease in the insulin content of the pancreas in dogs, so called therapeutic doses over long periods of time had no such effect Although the observations suggest a stimulating effect on the beta cells, the findings are not altogether consistent It is agreed that carbutamide and tolbutamide have no effect on the blood sugar level in the absence of insulin The question of whether insulin action is potentiated by these preparations cannot be satisfactorily answered by the clinical observations or animal experiments reported to date Insulin and the sulfonylureas differ in their effect on blood pyruvate The adrenalectomized animal (dog, cat, rat) treated with sulfonylureas has shown an exaggerated hypoglycemic response whereas the hypophysectomized animal has not Thus, the response of such animals to these drugs is different from their response to insulin The failure of hypophysectomized animals to display extreme hypoglycemia after administration of the drugs appears to be inconsistent with the previously cited studies suggesting stimulation of beta-cell activity

Prolonged administration of sulfonylurea compounds has resulted in thyroid hyperplasia, at least in animals, and with carbutamide, in a decrease in uptake of radioiodine by the thyroid in man Data thus far reported indicate that the drugs being studied have no measurable effect on the anterior hypophysis or the adrenal cortex of man or animals

Previous experience indicating that the drugs are most effective in older, obese patients with mild diabetes of relatively short duration has been confirmed They have some hypoglycemic activity in exceptional cases of juvenile diabetes Short-term tests of response to the drugs are moderately useful, but not infallible, in predicting a favorable result of maintenance therapy Side-reactions have consisted chiefly of skin rashes, gastrointestinal disturbances, leukopenia and generalized allergy, in the order given Well-marked hypoglemic reactions have been reported in several patients given drug therapy without injected insulin There have been reports of 8 deaths during treatment, with 2 each ascribed to sulfonamide sensitivity and liver involvement

SURGERY

Arterial Embolism H B Shumacker Jr and H S Jacobson Ann Surg 145 145-152 (Feb) 1957 [Philadelphia]

The experiences of the department of surgery at the Indiana University Medical Center with arterial embolism to the aorta and peripheral arteries, excluding only those to the brain and viscera, over a period of about 8 years have been studied in relation to the factors influencing the outcome The 55 patients (65 ischemic limbs) fell into two groups (1) 34 who were treated by direct arterial surgery and (2) 21 not so treated The results in the group of patients not operated on were poor Four of the 21 patients (19%) died Amputation was required in 13 of the 26 affected extremities and would probably have been required in 3 more if 2 other patients had survived Two patients with impaired circulation but with viable extremities after embolism obtained good results from sympathetic denervation Five additional patients survived with fair circulation Reasonably satisfactory circulation followed, therefore, in only 27% of the 26 affected limbs

Far better results were obtained in the group treated by arterial surgery The mortality was no higher than in the other group, only 7 (20 5%) of the 34 patients having died The circulation was adequately restored in 79% (31) of the 39 ischemic limbs in this group in contrast to the rate of only 27% in the other The mortality in both groups seemed to be related to the underlying disease and to the age of the patient It was comparatively low in patients with rheumatic heart disease and much higher in patients with other basic diseases, as is shown by the occurrence of only 2 deaths (7%) in 27 patients with rheumatic heart disease as compared with 6 deaths (26%) in 23 patients with arteriosclerotic heart disease, hypertensive heart disease, and myocardial infarction

Patients with *embolism to the main arteries of the arm* should not be neglected because of an optimistic feeling that the affected extremities are almost certain to survive with adequate circulation Amputation was required in 4 of 6 such patients not treated by embolectomy, and a 5th died with apparently satisfactory circulation The results of embolectomy are the better the sooner the operation is performed, but excellent restoration of circulation can be secured even as late as 48 hours after embolism because survival of the limb depends primarily not on the interval between embolism and operation but on the presence or absence of propagated thrombus in the distal arterial tree Experience gained in this study suggests that, when patients with impaired circulation but with still viable extremities are treated much later after embolism, a bypass grafting procedure may be preferable to embolectomy

Development of Cancer in Mixed Tumors of Salivary Glands E S Judd Postgrad Med 21 112-116 (Feb) 1957 [Minneapolis, Minn]

Two hundred ninety-six patients with primary mixed tumor of the parotid gland were followed up for long periods Four died of factors associated with their tumors, such as repeated local recurrence with deep invasion and hemorrhage Eighty percent of parotid tumors are mixed tumors They are benign and remain so Certain mixed tumors may be benign for many years Then a malignant change may suddenly occur The histological findings in these tumors of the parotid or submaxillary gland are identical Radical removal of submaxillary tumors, which is accomplished readily, is to be contrasted with the frequently inadequate extirpation of parotid tumors The rate of recurrence of mixed tumors is reduced by radical removal that permits nearly complete treatment when cancer is discovered

The Importance of the Emotional Factor in Rhinoplastic Procedures F T Hill J Maine M A 48 41-43 (Feb) 1957 [Brunswick, Maine]

Rhinoplastic procedures were performed in 4 patients—a young married woman, a 51-year-old woman, a 17-year-old girl, and a 20-year-old man The 1st patient had a lateral displacement of the nasal bone caused by an old fracture There was no functional disability Apparently she was much disturbed by the appearance of her nose and requested that it be corrected A Joseph type of rhinoplasty restored the nose to a symmetrical midline position, but it did not solve her mental problem, and a year later the patient took her own life The 2nd patient had sustained a severe compound fracture of the nasal and maxillary bones as a result of a fall While fairly satisfactory symmetry was obtained by surgery, it was not perfect as the entire right nasal bone was destroyed in the accident This patient was quite content with the result, proving that the emotional factor generally is of less importance in the traumatic type of case when repair is imperative, recovery from the injury with its fear of unsightly deformity makes any improvement more readily acceptable

The 3rd patient had a beautiful face, marred only by a severe saddleback deformity of the nose She was shy and easily embarrassed, had a tendency to withdraw from her playmates, and had a marked inferiority complex A rhinoplasty using a bone graft from the pelvic brim inserted through a vestibular incision, corrected the deformity, without any external scar Correction of the deformity gave the patient confidence in herself No longer backward and shy, she took her rightful place in her young world The 4th patient had an exaggerated "corkscrew" type of nose with almost complete nasal obstruction The butt of jokes and horseplay at the hands of his contemporaries and adults, he had left school at an early age and had a menial job sweeping the floors of a factory Improvement of the facial contour, obtained by a rhinoplasty in 2 stages, made the patient a changed person—more extraversive and sociable

These cases are cited to show the significance of the emotional status of the patient in determining the success or failure of rhinoplastic procedures Except for traumatic cases of comparatively recent origin, the psychological factor assumes the greatest importance in the decision for or against rhinoplasty Mere desire for alteration of facial contour, when there is little or no interference with function should be viewed with caution On the other hand, attempts to correct abnormalities of function may fail if an accompanying external deformity is neglected The importance of gross deformities, especially in the young and the effect on the personality of the patient are illustrated by the cases of the last 2 patients

Low Hemoglobin Levels in Men G W Hervey, E P Adashek and S T Gibson Am J M Sc 233 126-130 (Feb) 1957 [Philadelphia]

Presumably, the men who volunteer to give blood for medical use feel physically able In the course of 2 or 3 weeks, persons between the ages of 18 and 60 years present themselves in adequate numbers and from adequately diverse social and economic backgrounds to represent the larger population stratum from which male donors come They do not typify the corresponding general male population, since the latter embraces not only seemingly healthy men but also the hospitalized, the ill but not hospitalized, and others who for physical or medical reasons refrain from coming to blood collection centers This distinction should be remembered when contemplating the fact that, even though the men who respond may be considered above average from the standpoint of apparent health, low hemoglobin levels cause numerous persons to be disqualified Data pertaining to 4,993 men who volunteered to give blood in Los Angeles in July, 1955, disclose that low hemoglobin levels caused 8 17% to be disqualified This, compared with about 4% for a sample of 14,304 men reporting in January, 1956 indicates a strong seasonal variation The July data appear to signify that, mainly as the result of self-screening by many Los Angeles donors, the more numerous the past donations the fewer were the rejections Persisting against such selectivity, however, the percentage of disqualifications in general tended to be higher for older men Persons who, having previously given blood, waited at least 4 months before again donating were rejected less often than those returning in less than 4 months The authors caution against placing cause-and-effect interpretations on the relations revealed by such mass data and stress the need of further study to establish possible connections between environmental factors and the incidence of low hemoglobin levels

Air Embolism in Course of Pneumoperitoneum Precautions Against It P E Guarinello Rev brasil tuberc 25 119-130 (Jan) 1957 (In Portuguese) [Rio de Janeiro]

Air embolism is the most serious complication of pneumoperitoneum In some patients the symptoms may appear as simple syncope immediately followed by severe or even fulminant symptoms In others the symptoms are fulminant at the onset Cardiac, respiratory, and cerebral symptoms appear simultaneously the cerebral symptoms predominating The author reports 5 cases of air embolism occurring in a series of 127 pneumoperitoneums The condition was benign in 3 patients, severe in 1, and fulminant in 1 After the occurrence of these 5 cases, the author evolved a technique that consists of injecting air at a rate of not more than 20 cc per minute The injections are always given on the left side, near or below the umbilicus If symptoms suggesting air embolism appear, the procedure is immediately stopped and resumed a few days later In 4 of the authors patients air embolism occurred when the quantity of air injected reached between 60 and 180 cc In the fatal case with a fulminant course, the embolism occurred when the quantity of air injected reached 180 cc The treatment consisted in placing the patients immediately in an extreme Trendelenburg position and giving cardiac stimulants

Results of Surgical Treatment of the Postcholecystectomy Syndrome K Lehmann Acta chir scandinav 112 40-46 (No 1) 1956 (In English) [Stockholm, Sweden]

A follow-up examination of 94 patients treated for postcholecystectomy syndrome revealed that 54 required a second operation Explorative choledochotomy was performed on 8 Transduodenal splitting of Oddi s sphincter was tried in 5 patients Anastomosis between the deep bile ducts and the duodenum was performed on 26 Calculi were found in the remaining 15 patients, and they made a complete recovery Less than 50% of the patients improved after the other operations Persistent pains recurred despite the presence of a well-functioning anastomosis, as proved by cholangiography The correctness of the theory of dyskinesia of Oddi s sphincter was not confirmed by the author, since no improvement was seen after this operation The poor results that were obtained in 24 of the patients was due to their psychic conditions 9 proved to be drug addicts, and 15 had various mental disorders Reoperation should be limited to patients whose complaints have a definite organic basis and in whom stones are present

Surgical Treatment of Lymphedema of the Upper Extremities G H Pratt and A A Levine A M A Arch Surg 74 183-188 (Feb) 1957 [Chicago]

Lymphedema in the upper extremity is often caused by carcinoma of the breast Congenital lymphatic collections may occur as a cystic hygroma or the essential or Milroy's type A nonmalignant lymphedema of the upper extremity may follow radical breast operations, owing to operative trauma and the removal of the lymph channels and nodes There may also be edema from some temporary interference with the venous return Low-grade infection, too, may cause temporary postoperative swelling This paper deals with lymphedema of the traumatic as well as the congenital type The symptoms are mainly a massive enlargement of the part To this swelling are added skin changes, muscular atrophy, and sometimes damage to nerves from pressure and a pull on the shoulder girdle The lymph accumulates in the skin, fat, and superficial and deep fascia but rarely in the muscle The edema due to interference with the venous return can be treated by elevation and support For the lymphedema due to infection the use of antibiotics is helpful If malignancy involves the nodes and has not been completely removed, the lymphedema will progress The authors found and reported previously that the lymph collections in lymphedema begin from 0 4 to 0 5 mm beneath the epidermal layer The superficial epidermis is not diseased and can be removed by the electric dermatome at a depth of 0 038 mm The rest of the superficial and deep fascia is excised to remove all fatty tissue, even that between the muscles The epidermis is replaced directly on the denuded muscles The principle of this operation is to remove the skin in such thin layers that it is free from lymphatic accumulation

A case is reported to illustrate how extensive nonmalignant lymphedema of the arm can become Swelling in the left hand and arm had developed in this woman after a radical mastectomy for mammary carcinoma 12 years earlier After deep x-ray treatment, the swelling of the arm became progressively worse It was necessary for an attendant to carry her arm The skin was removed at 0 038 mm The lymph, fat, and superficial and deep fascia were excised and a skin graft applied The operation was performed in 2 stages Exactly how much lymph tissue was removed is unknown, but the patient lost 90 lb (40 8 kg) in weight So much fluid ran out during the operation that the surgeon and his assistants were literally soaked in lymph The operation was effective and has been performed on 14 other patients After the operation the part must be supported Hyperkeratinization often develops, and, since the epithelial layer is thin, it frequently heaps up with keloids Dermatitis develops, and the patients are subject to fungus infections, which are controlled with soaks of mild solutions of potassium permanganate Care must be taken to prevent contracture of the fingers, elbow, and shoulder during recovery Since the lymph defense is removed, antibiotics often are required in patients with repeated attacks of sepsis

Fatal Pseudomonas Septicemias in Burned Patients K Markley, G Gurmendi, P M Chavez and A Bazan Ann Surg 145 175-181 (Feb) 1957 [Philadelphia]

One of the major difficulties encountered in the course of the Peru burn project was a high late mortality, especially in burned children The problem of late deaths after burns has been especially serious in Peru because of the high incidence of fatal Pseudomonas aeruginosa (Bacillus pyocyaneus) septicemias A characteristic skin lesion appearing in the nonburned area was frequently associated with the Ps aeruginosa septicemia seen in Peru The study group consisted of 172 children and 103 adults with burns involving 10% or more of the body surface Ps aeruginosa septicemia in 29 of the children and 3 of the adults was accompanied by the development of cutaneous lesions in the nonburned area The lesions were usually vesicular or nodular Some patients had both types The vesicular type, which occurred in 72% of the children with cutaneous lesions, usually appeared from 3 to 8 days after burning, although in a few rare cases it was observed between the 8th and 43rd day after the burns were sustained The initial vesicle was followed in rapid succession by many others of the same kind in nonburned areas Only 1 patient had lesions (2) of this type in the burned area No lesions were found on the mucosa, soles, or palms Death generally occurred from 24 to 48 hours after the appearance of the first vesicle

Subcutaneous nodules appeared in the other 28% of the patients with cutaneous lesions, coming on at any time from the 5th to the 28th day after burning Several such nodules were usually present, but their number was always much less than that of the superficial necrotic type The condition of these patients for the most part deteriorated less rapidly than that of the others, death occurring from 2 to 12 days after the appearance of the first nodule The patients had temperatures up to 39 C (102 2 F), great thirst, marked abdominal distention, and depression of the central nervous system regardless of the type of skin lesion Death was preceded by coma, subnormal body temperatures, rapid and shallow respiration, and progressive circulatory failure that led to death in shock

Laboratory studies revealed anemia and hypoproteinemia in every patient, and evidence of hyponatremia, hyperkalemia, and metabolic acidosis was almost always present Characteristic hemorrhagic and necrotic lesions were also found in the viscera of 34 badly burned patients at autopsy Negative blood cultures for Ps aeruginosa were found in only 3 children in the entire group of 29 children and 3 adults with skin lesions Not all of the patients who died from Ps aeruginosa septicemia, however, presented cutaneous or visceral lesions, only 22 of 28 badly burned patients with blood cultures positive for Ps aeruginosa who came to autopsy between 1951 and 1956 presented such lesions No effective therapy has been found to prevent the death of patients with Ps aeruginosa septicemia An attempt is now being made to prevent the development of septicemia by the prophylactic administration of polymixin after the patient has passed the first 48-hour period

NEUROLOGY & PSYCHIATRY

Three Hundred Alcoholics Treated in a Psychiatric Hospital P Bernard, R Lecuyer and G Bles Semaine méd [Suppl to Semaine hôp Paris] 33 45-49 (Jan 14) 1957 (In French) [Paris]

Three hundred men with alcoholism were treated at a psychiatric hospital between May 1, 1955, and Aug 15, 1956 The largest number of patients (50 54%) were between the ages of 40 and 50 years, 21 86% were between 30 and 40, 7 88% were less than 30 years of age, and 19 72% were over 50 years of age Detoxication treatment was given for the first time to 76 33% of the patients, and 23 67% had been detoxified on previous occasions at the same hospital or at other hospitals The patients were subdivided into 3 groups according to their clinical conditions The 1st group (78 70% of the patients) were in a state of alcoholic intoxication but did not have mental disturbances in the usual sense, except for temporary confusion The 2nd group (17 87%) had primary mental disturbances that became manifest after detoxication treatment and after the disappearance of the symptoms directly caused by alcohol Definite backwardness, neuroses or psychoses, and a demented state were observed The last group (3 43%) did not show clear signs of intoxication, and their hospitalization was justified only by their pathological drunkenness At least 50% of the patients had a family history of alcoholism Sexual activity was reduced in 76% of the patients and 14% were impotent The prospect of restoration of the patient's virility may play an important factor in getting him to cooperate with treatment Seventy-three per cent of the patients were married with families of 3 or more children and nearly all of the patients had reactions of jealousy This assumed the form of delirious ideas in only 2 5% Sexual perversion was observed rarely

The average duration of hospitalization was 34 days for those who were admitted for the 1st time and 44 days for those with a recurrence of alcoholism Treatment consisted of 2 phases The 1st phase was that of detoxication in the proper sense and consisted of a 10-day course of administration of strychnine in doses varying from 5 to 40 mg per day, large doses of liver extracts, vitamin B in doses of from 100 to 200 mg per day, and lipotropic factors given orally Chlorpromazine was given to all patients with pronounced agitation and anxiety Penicillin was given when an infection was suspected Patients in poor general condition were given combined vitamins A, B_2, B_6, B_{12}, C and D Fever, confusion and agitation occasionally necessitated rest in bed The 2nd phase of treatment consisted of the administration of disulfiram On discharge, an average maintenance dose of 250 mg f disulfiram was prescribed for 6 months and one of 25 mg for the following year Complete and permaent abstinence is imperative The period of treatment n the hospital is short as compared with the entire duration of treatment Prolonged treatment in the hospital does not seem useful except for dangerous patients, atients in an extremely poor general condition, and ose with recurrences of alcoholism The alcoholics hould not be treated in a psychiatric ward but rather n an annex or in a specialized center

eurological Manifestations of Acute Porphyria The olyneuritic Form with a Cyclic Course Clinical and rognostic Remarks Concerning 7 Cases M Bonuelle, P Bouygues and H Puech Presse med 65 199-02 (Feb 2) 1957 (In French) [Paris]

The authors report on 7 patients between the ages f 25 and 48 years with acute porphyria, which was onfirmed in all by the presence of large amounts of orphyrins in the urine and, particularly, by a strongly ositive reaction to the porphobilinogen test One of he 7 patients did not have any neuritic symptoms nd was included only because his digestive disurbance was associated with insomnia, which was lso a constant symptom in the other 6 patients with he polyneuritic form of the disease The cyclic type f its clinical course consisted of a preparalytic stage, he onset of which was characterized by digestive disurbances with constipation in all 6 patients and vomiting in 5 Diarrhea preceded constipation for 3 days n 1 patient Simultaneously with these digestive ymptoms or several hours or days later, psychic disurbances and insomnia occurred and were associated with a rise in temperature to 38 C (100 4 F), oliguria, moderate arterial hypertension, and tachycardia in ll the patients and amenorrhea in the women

Paralysis appeared within the 30th to the 40th day, nd it progressed within a period of 5 to 10 days to omplete quadriplegia in 2 patients, while it was imited to certain muscle groups in the other 4 patients, with a predominance in the muscles of the houlder girdle, the triceps, and the extensors of the and The cranial nerves were involved in several patients, with bilateral facial paresis in 2, diplopia in 1, isturbances of deglutition in 3, and disturbances of honation in 3 There is the risk of respiratory disurbances that occurred in 2 of the 6 patients The espiratory disturbance lasted for from 15 to 30 minutes, occurred repeatedly, but remained purely subjective in 1 of the 2 patients The respiratory disturbance was severe in the other patient, and artificial espiration combined with tracheostomy was required o save the patient's life

After the paralysis had reached its maximum, there was a period of about 2 weeks of latent regression Then slow but definite regression began, which lasted or 5 to 14 months, and complete motor recuperation occurred in all the patients One of the 6 patients had a 1st attack of quadriplegia 2 years before that reported on, and the other 5 patients all had their 1st attack of the polyneuritic form of porphyria An early recurrence including digestive and psychic disturbances, fever, oliguria, and a short partial aggravation of the paretic symptoms occurred in 2 patients, a late recurrence of quadriplegia after 4 years in 1, a recurrence of purely psychiatric type in 1, and a recurrence of the digestive disorders in 2 In addition to these early and late genuine recurrences, successive bouts of digestive and psychic disturbances occurred occasionally during the paralytic stage of the disease, thus masking the cyclic course of the disease The survival of all 7 patients suggests that the notion of a definitely poor prognosis that had previously been maintained by other workers should be reconsidered

GYNECOLOGY & OBSTETRICS

Pregnancy in Diabetic Women An Analysis of a Series C Boughton and E Perkins J Obst & Gynæc Brit Emp 64 105-112 (Feb) 1957 [London]

Commenting on the incidence of diabetes in pregnant women, the authors state that, among 7,680 deliveries at St Thomas's Hospital in London, there were 30 in diabetic women, an incidence of 1 in 256 The authors examined a series of women in whom the diabetes had been treated by the free diet" method to determine if this had any apparent effect on the maternal or fetal mortality or on the incidence of toxemia in pregnancy This series comprises 51 pregnancies reaching viable stage in 29 women with diabetes Each patient was supervised at the antenatal clinic as soon as pregnancy was diagnosed, usually before the 12th week, after which the women attended both the diabetic and antenatal clinics All women required insulin throughout pregnancy or in the 2nd or 3rd trimesters, and it was given either as soluble insulin or as one of the long-acting preparations In all patients treatment was changed to soluble insulin at the time of delivery or in the event of any operation involving the administration of a general anesthetic The composition of diet was largely left to appetite, and, except in obese patients, no restriction was placed on the caloric intake or on the form in which carbohydrate foods were taken

The spontaneous abortion rate in this series was about 22%, which is approximately double the usually expected figure for nondiabetic women Preeclamptic toxemia was observed in 21 of the 51 instances, and hypertension alone was observed in 1 Pregnancy had to be terminated in 2 women Hydramnios occurred in 17 of the 51 pregnancies, and it was associated with toxemia in 7 Of the 3 congenital abnormalities only 1 was associated with hydramnios Insulin requirements rose during the 2nd and 3rd trimesters in 82 5% of the patients, remained unchanged in 12 5%, and fell in 5% Mild ketonuria was not uncommon in the later stages of pregnancy Fetal deaths occurred in 15 of 51 viable pregnancies (those of over 28 weeks' duration), 7 of these were intrauterine deaths, 3 were stillbirths, 3 were neonatal deaths, and 2 occurred during hysterotomy Intrauterine death occurred between the 28th and 36th weeks in 6 of the 7, and it was almost invariably associated with toxemia As the toxemia factor was associated with more than 50% of the total number of fetal deaths, any measure that reduces the incidence of toxemia should reduce the fetal loss The fetal mortality in this series seemed to bear no relationship to the severity or duration of the mother s diabetes All the multiparous women who lost babies had unfortunate obstetric histories, whereas, in the 23 successful pregnancies in multiparas, only 7 had had a previous pregnancy resulting in stillbirth or intrauterine death The authors believe that the dietetic method of treatment using the restriction of salt and caloric intakes should be investigated

10,000 Minor Gynecologic Operations on an Outpatient Basis J Vermeeren, R R Chamberlain and R W Te Linde *Obst & Gynec* 9 139-142 (Feb) 1957 [New York]

Minor gynecologic procedures requiring general anesthesia, such as dilatation and curettage, were done as an outpatient service in 10,000 women in the course of more than 15 years This service is feasible wherever operating suites are equipped with recovery rooms In the year 1953, chosen for random sampling, 1,150 gynecologic patients were anesthetized and allowed to go home on the same day This represents 70% of the minor surgical procedures performed in the gynecologic department in that year Of the 1,150 patients, 908 are reported on in detail Indications for operation consisted of menorrhagia and/or metrorrhagia in 454, infertility in 215, postmenopausal bleeding in 56, incomplete abortion in 20, and miscellaneous in 163 Thiopental sodium supplemented with nitrous oxide and oxygen was the anesthetic used in more than 98% of the patients The average time of anesthesia was 20 minutes Curettages were performed on 803 patients, and a cervical biopsy was included in the curettage in most of them Cauterization of the cervix was also carried out in 119 patients Malignancies were detected in 18 of the 908 patients

There were 16 unplanned immediate admissions to the hospital after the operative procedure, 6 for perforated uterus at the time of the curettage, 1 for severe uterine bleeding, 5 for possible ectopic pregnancy, 1 for possible ovarian tumor, and 3 because the patients took the anesthesia poorly There were 8 unplanned delayed admissions to the hospital from 1 to 42 days after the operative procedure, 2 of these were for bleeding from cervical biopsy sites, 1 because of a pathological report of decidua without chorionic villi in curettings, 1 for ruptured ectopic pregnancy, 2 for continued uterine bleeding after curettage, 1 for abdominal pain, and 1 for an adnexal mass detected on follow-up examination Of the 908 patients, 25 had made previous arrangements to stay in the hospital after their minor operation for 24-hour observation or for further studies Thus, 883 patients attempted to undergo minor gynecologic operations on an outpatient basis and 859 went home without complication within a few hours after the operation This form of service is recommended to other hospitals to conserve hospital beds, nursing service, and the patient's time and money

An Estrogen with Prolonged Action Estradiolcyclopentylpropionate (ECPP) Clinical Observations M Mayer and X Camenen *Semaine hôp Paris* 33 327-332 (Jan 26) 1957 (In French) [Paris]

Experiments on young and castrated rats demonstrated that 17-β-cyclopentylpropionate of estradiol (ECPP), a new estrogen, is superior to the benzoate of estradiol in that it has a more prolonged action The authors were able to observe the clinical effects of this new drug in 53 women The patients included women who had been subjected to total or subtotal hysterectomies with removal of both ovaries, women with disturbances caused by the natural menopause, women with amenorrhea or hypomenorrhea, and women with frigidity The substance has a decided estrogenic effect, its action is prolonged, and it has no undesirable secondary effects The estrogenic effect is most pronounced between the 5th and 10th days after the intramuscular injection It is advisable to inject small initial doses, 5 mg proved more effective at the onset than 25 mg Late estrogenic activity persisted 15 days with 5 mg and 2 months with 25 mg Small repeated doses had a late action that was more and more prolonged

The drug proved highly effective in disorders caused by castration and by the menopause While it increased the menstrual flow, it did not cause menorrhagia, probably because of its gradual, slow, and prolonged action It proved effective in some cases of eczema with menstrual exacerbation, in vulval pruritus, and in migraine of the menstrual type While it increased appetite and, therefore, body weight, it did not cause significant water retention The authors recommend the following dosages for frigidity 5 mg once or twice a month, preferably on the 8th day of the cycle in amenorrhea or hypomenorrhea 5 mg every 10 days, and in severe disturbances due to ovarian deficiency an injection of 20 mg about once in 2 months

Clinical Significance of Weight Trends During Pregnancy A M Thomson and W Z Billewicz *Brit M J* 1 243-247 (Feb 2) 1957 [London]

Women who were pregnant for the first time and who were not subjected to weight regulation were weighed at the first antenatal visit, usually in the 13th week of pregnancy, and, again, as a rule, from 4 to 6 weeks later Most of them were then weighed monthly until from the 28th to 30th weeks of pregnancy and more often during the final weeks Women with multiple pregnancies were excluded from the study For each woman, weights in the 13th, 20th, 30th, and 36th weeks were determined by interpolation if necessary, and the average weekly rates of gain in the 3 intervening periods calculated These average weekly rates of gain in 4,214 pregnant women were the data used The number of women in each period differed, because some women had not reported early enough, were delivered too early, or were weighed too irregularly for inclusion in all 3 periods The pregnant women were divided in 3 clinical groups 6 5% had preeclampsia with albuminuria, 25 4% had hypertensive complications, mostly mild preeclampsia without albuminuria, and 68 1% had normal blood pressure

The average rate of gain was higher in women with preeclampsia than in those with normal pregnancy, and the incidence of preeclampsia rose as the rate of weight gain increased These facts are of little value for predicting preeclampsia in the individual woman The incidence of prematurity was highest when weight gains were consistently low, dropped as the rate of weight gain increased, and then rose again with high rates of gain Preeclampsia was an important cause of prematurity in the high weight-gain groups but not in those with low weight gain The most favorable outcome of pregnancy—in terms of preeclampsia, prematurity, and perinatal death—was associated with a moderate rate of weight gain, at least throughout the 2nd half of pregnancy A gain of about 1 lb (454 Gm) a week is suggested as a sound and realistic average to aim at The more rigorous restriction of weight gain that has been advocated is not justified on present evidence and may be harmful

PEDIATRICS

Cardiac Murmurs in School Children D Stuckey, B Dowd and H Walsh M J Australia 1 36-38 (Jan 12) 1957 [Sydney, Australia]

During the survey reported, the school medical officers referred for further investigation every child considered to have a cardiac murmur at routine medical examination The total number of children examined was 34,863 The two sexes were almost equally represented in this sample, and the ages ranged from 5 to 16 years The total number of children reported to have a cardiac murmur was 467 (1 34%), and, of these, 364 were further investigated at one of the special centers If the relative incidence of the various forms of heart disease in the remaining 103 children may be assumed to be the same as in the 364, the incidence figures for the 34,863 children included in the survey were as follows rheumatic heart disease 1 4 per 1,000, congenital heart disease 2 8 per 1,000, and functional systolic murmurs 9 0 per 1,000 Of every 10 children found to have cardiac murmurs, 1 had rheumatic heart disease, 2 had congenital heart defects, and the remaining 7 presumably had normal hearts The incidence of all forms of organic heart disease in school children in this survey (4 2 per 1,000) is much the same as previous figures reported in Australia Some figures for similar types of school surveys are 5 0 per 1,000 in New York, 3 6 per 1,000 in San Francisco, 5 3 per 1,000 in Cincinnati, 4 4 per 1,000 in San Francisco in another study, and 3 6 per 1,000 in Toronto It must be remembered that these figures do not indicate the total incidence of organic heart disease in childhood, for no account is taken of children being treated in hospitals or at home who are unable to attend school

The Relative Values of Streptomycin and Isoniazid in the Treatment of Tuberculous Meningitis in Children B Ratner, G R Klimkievicz, W C Ellis and others Sea View Hosp Bull 16 103-115 (Jan) 1957 [New York]

In a recent review reporting on 420 children with tuberculous meningitis who were treated with streptomycin, the recovery rate was 15% in 1947, 30% in 1948, and 46% in 1949 The rate rose to 50% in 1950 when aminosalicylic acid (PAS) was given additionally Treatment with isoniazid in addition to streptomycin raised the recovery rate to 71% in 1952 The use of streptomycin had often led to sequelae, such as deafness, blindness, and hydrocephalus The authors' investigations started at the end of 1951 Twenty-one patients, between the ages of 8 months and 12½ years, with tuberculous meningitis were treated with isoniazid Two infants were given isoniazid alone from the inception of their ailments The spinal fluid returned to normal within 4 months One child was kept on isoniazid therapy for 13 months and observed for 2 years and 7 months after the treatment had been discontinued The other was treated for 6½ months and observed for 3 years and 7 months without therapy Eleven children, whose conditions were poor while they were on streptomycin and/or PAS therapy, were given isoniazid alone for an average period of 18 months The spinal fluid became normal within 7 months All these patients made a complete recovery Five patients developed severe residua after treatment with streptomycin They were placed on therapy with isoniazid alone, but the drug did not correct the damage done by the streptomycin therapy Isoniazid failed to prevent death in 3 patients previously treated with streptomycin Hydrocephalus and advanced meningitis were the causes of death in 2 patients The 3rd, who apparently was recovering from meningitis, broke a leg at this time His spinal fluid was positive for Mycobacterium tuberculosis and he subsequently died The recovery rate of this series of patients is 86% Isoniazid given alone for the treatment of tuberculous meningitis appears to be superior to streptomycin alone or in combination with other drugs Isoniazid is not responsible for neurological residua resulting from the use of streptomycin

Problems in the Management of Bladder Neck Obstruction in Children E Burns and P Shashy Ohio M J 53 170-175 (Feb) 1957 [Columbus, Ohio]

A review of the findings in 110 private patients with nonneurogenic obstruction treated surgically indicates that most of the problems encountered result from delayed recognition This delay is apparently due to failure to consider the possibility of an obstructive lesion in children who have abnormalities in the voiding pattern In the cases reviewed the following symptoms were recorded urgency and frequency of urination, straining to urinate, enuresis, fever of unexplained origin, recurrent or persistent pyuria, overflow incontinence, acute urinary retention, and hematuria Any of these symptoms are an indication for a study of the urinary tract Frequency and straining are early symptoms, and, if the obstruction is severe, they should be observed during the 1st year of life, not infrequently during the first 6 months Wetting the diaper at abnormally frequent intervals may be noted, and straining to urinate is often indicated by a purplish discoloration of the face during the voiding act Enuresis is not always merely a functional disorder Slightly more than 28% of children with enuresis examined by the authors had some type of obstructive lesion of the lower part of the urinary tract Medical treatment and psychotherapy are frequently carried out for too long a time

Three types of obstructive lesions at the neck of the bladder are encountered in children The commonest type is contracture of the internal sphincter Congenital prostatic valves were formerly thought to be common but are now considered almost as rare as congenital hypertrophy of the verumontanum as a cause of obstruction of the bladder neck in children Ureterocele and stenosis of the external urethral meatus are other possible obstructive lesions of the bladder neck in children The condition is not difficult to diagnose Chemical and bacteriological examinations of the urine, renal function tests, cystourethroscopic examination, and roentgenographic examinations, including excretory urograms, retrograde cystograms, and retrograde pyeloureterograms are made as indicated in the individual case Treatment consists in surgical removal of the primary lesion by either transurethral resection or suprapubic transvesical excision Associated lesions or secondary complications should also be corrected surgically when necessary

THERAPEUTICS

Therapy of Diabetes Clinical Experiences with Hypoglycemia Inducing Sulfonamides W Brednow and D Jorke *Munchen med Wchnschr* 99 101-105 (Jan 25) 1957 (In German) [Munich, Germany]

Brednow and Jorke present their observations on 50 diabetic patients with 2 new brands of carbutamide, Invenol and Oranil Patients with a mild form of diabetes, who respond to dietetic restriction of carbohydrates, should not be treated with sulfonamides Although the orally effective antidiabetic sulfonamides reduce the blood sugar after a few hours, 6 or 7 days may be required for their complete elimination Because the effect of insulin is more easily controlled, the authors prefer insulin to the sulfonamides in diabetic patients who are to be operated on Furthermore, since the prolonged effect of the sulfonamides depends at least partly on the increased tubular reabsorption, patients with diabetic nephropathy should be excluded from sulfonamide therapy Patients with precoma and coma also are more responsive to treatment with regular insulin With these facts in mind, the authors excluded 15 of their 50 diabetic patients from treatment with sulfonamides because 7 of them responded to dietetic treatment and in 8 others a change from insulin to sulfonamide treatment seemed inadvisable

Of the remaining 35 patients, 21 responded well to the exclusive use of Invenol or Oranil, in 3 others these drugs had to be combined with insulin, and in the remaining 11 patients they failed The authors found that a gradual changeover from insulin to oral sulfonamide therapy is possible even after diabetes has existed for many years, but, on the other hand an abrupt changeover from insulin to sulfonamide medication may lead to serious disturbances in carbohydrate metabolism The hypoglycemia-inducing sulfonamides seem particularly valuable in elderly diabetics, in whom the diabetic disturbance is more of the countergegulatory type rather than due to pancreatic factors Nineteen of the 21 patients who responded favorably to the sulfonamides were over 50 years of age It was noted also that intercurrent and chronic infections may block the antidiabetic effect of the sulfonamides The question of the combined use of insulin and the carbutamides may prove difficult, but the authors found that 1 young person with a highly unstable diabetes who failed to respond to insulin or a carbutamide alone did respond to a combination of the 2 Few complications resulted from the use of Invenol and Oranil, and the authors conclude that oral therapy with sulfonamides is possible in a large percentage of diabetics and that it has advantages over injection therapy

Therapeutic Attempts in Secondary Cancer of the Lung A Meyer, O Monod, M Brunel and others *Presse méd* 65 128-131 (Jan 23) 1957 (In French) [Paris]

Various treatments for secondary cancer of the lung are available Radiotherapy still has a transitory and palliative action on secondary pulmonary cancers, although its action may be beneficial and prolonged in many cases Good results are also obtained by treatment with radioactive sodium iodide (I^{131}) The authors report on a 58-year-old man with metastatic pulmonary cancer of prostatic origin He had been given diethylstilbestrol since 1951 Two months after hormonal treatment was started, the radiologic shadows in the lung disappeared The patient has continued to take diethylstilbestrol but in reduced doses His general condition and that of his lungs were perfect at the time of his last checkup Chemotherapy was of no benefit in patients with secondary cancer of the lung Surgical removal was performed on 10 patients with metastatic cancer of the lung of various origins Three of them died a few months after operation, 3 could not be traced, and 1 patient was only recently operated on, so that no conclusion regarding treatment could be drawn Two patients were in excellent condition 2½ years after their operation Primary cancer should be removed if possible, but metastatic pulmonary cancer should also be removed even if its origin is unknown This cancer usually is localized so that lobectomy or even more limited excision should be performed The difference between embolism of cancerous cells in the pulmonary capillaries and the true metastatic tumor, which practically has the characteristics of an isolated tumor, is emphasized

Benzathine Penicillin G in the Treatment of Syphilis

C A Smith, M Kamp, S Olansky and E V Price Bull World Health Organ 15 1087-1096 (No 6) 1956 (In English) [Geneva]

Smith and associates found that observations over a period of 2 years confirmed preliminary data indicating that a single injection of 2,500,000 units of benzathine penicillin G maintains in most patients a detectable blood level for periods up to 4 weeks They found this preparation highly effective in the treatment of primary and secondary syphilis In these forms of syphilis it produces results equal or superior to those obtained with schedules providing 4,800,000 units of procaine penicillin G in oil with 2% aluminum monostearate (PAM) The authors also present in this report their experience with benzathine penicillin G in the treatment of asymptomatic neurosyphilis Preliminary data suggest that a single injection of 2,400,000 or 2,500,000 units of benzathine penicillin G may be inadequate for the treatment of asymptomatic neurosyphilis and that it may be necessary to increase the dose The long-sustained blood levels after the administration of benzathine penicillin G do not seem to produce delayed reactions, whereas repeated injections of PAM increase the risk of untoward reactions to treatment

PATHOLOGY

Viral Verrucae in the Anorectum with Consideration of the Cancer Problem

H M Young Surgery 41 292-305 (Feb) 1957 [St Louis]

Microscopic examination of tissues removed at anorectal surgery from 300 patients revealed warts in the anal canal, the anal crypts, or on the rectal mucous membrane Verrucae, or warts, were observed growing from the anal crypts The growth often plugged the crypt, thus impeding drainage and enchancing secondary bacterial infection Thrombosed anal varix, anal fissure or ulcer, and perianal or renal abscess with fistula formation were noted in many crypts Verrucae were detected on the tips and in the substance of hypertrophic anal papillae of patients with chronic anal cryptitis associated with papillitis Verrucae were found in the bed of anal fissures and in the underpocketed bases of distal sentinel tags Warts were identified in the involved crypts, which served as the primary orifices or points of origin of fistulas The verrucae were found in the substance of the cord-like tracts and were seen bulging from or plugging the secondary orifices of the fistulas

More than 200 of the 300 patients from whom the specimens were obtained had shorter than normal anal canals This may be a congenital variation that predisposes the patient to trauma, ectropion, and infection with bacterial, mycotic, and viral agents of the anorectum Verrucae in the anorectum may stimulate an antiviral or other immunological reaction There was no concomitant carcinoma in any of the 300 patients in whom warts were detected, although 28 had benign adenoma Conversely, there were no verrucae of the anorectum found in another series of 300 patients with carcinoma of the colon and anorectum The presence of warts in the anorectum and the absence of carcinoma in the intestine suggests the existence of a delicate immunological balance Should an interrelationship be definitely established, then a cancer detection test can be envisioned on this basis

Recognition and adequate treatment with podophyllin in acetone but not mineral oil and/or fulguration of warts and possible autogenous or smallpox vaccine are suggested Adequate treatment by preoperative management and by fulguration of verrucae at the time of surgery often enhances postoperative recovery in all types of anorectal surgery Postoperatively, unrecognized or superimposed verrucous infections cause indolent scar formation Heretofore, wounds considered to be an overgrowth of granulation tissue are now often known to be complicated by a viral wart formation The unstable herringbone pattern of the scar tissue on microscopic study furnishes evidence of an unrecognized or untreated verrucal involvement

The B C G Lesion in Sarcoidosis

P Forgacs, C K McDonald, M O Skelton Lancet 1 188-190 (Jan 26) 1957 [London]

It is widely believed that most cases of sarcoidosis represent a peculiar form of reaction to the tubercle bacillus The studies reported were undertaken to test this hypothesis by observing whether attenuated tubercle bacilli of the BCG strain survive when they are inoculated into the skin of patients with sarcoidosis This experiment also provided an opportunity to reexamine Lemming's claim that the histological pattern at the site of such an injection is peculiar to the disease and may lend support to the diagnosis Ten patients with sarcoidosis who volunteered for this investigation were given an intracutaneous injection of 0 1 ml of a BCG vaccine containing 0 5 mg of bacilli per milliliter The rate of development of the local reaction was recorded Six weeks later the skin at the site of vaccination was excised and subjected to bacteriological and histological examination The 8 women and 2 men had 2 or more of the clinical and radiologic manifestations of sarcoidosis In 5 uveitis was the presenting complaint, it was always associated with symmetrical enlargement of the hilar lymph nodes, reticulation of the lungs, or both The prevalence of uveitis and intrathoracic manifestations among the 10 patients studied is to be attributed to the fact that most of the patients were under the joint care of an eye hospital and a chest clinic

Seven patients had a delayed response to the intracutaneous reaction of the BCG suspension and 2 patients had an immediate reaction, while in 1 patient the rate of the development of the reaction was not recorded Bacteriological investigations demonstrated that attenuated tubercle bacilli survive in the skin of patients affected by sarcoidosis The bacilli are apparently unaffected by the passage, since their form, staining properties, rate of growth, and appearance in culture, as well as their power to induce tuberculin conversion in the guinea pig, were identical with those of the BCG strain obtained from other sources It is difficult to assess how far an experiment of this type approaches the conditions under which tubercle bacilli are supposed to initiate the cutaneous manifestations of sarcoidosis The number of bacilli injected was presumably far in excess of the number that might lodge in the skin by dissemination under natural conditions On the other hand, the bacterial population is known to decrease sharply soon after vaccination The histological appearance of the BCG lesion in sarcoidosis is not distinctive enough to be used as a diagnostic test The pattern is that of a chronic inflammation with histiocytes and lymphocytes predominating No tissue specimen showed the characteristic cell arrangement of the sarcoid follicle

ANESTHESIA

The Anæsthetic Management of a Severely Burnt Child A S M Lamont and V A Grimshaw Brit J Anæsth 29 25-27 (Jan) 1957 [Altrincham, England]

A 5-year-old child was hospitalized within 30 minutes after sustaining severe burns She was in shock, and so an intravenous drip was started at once, 7 5 mg of morphine being added to the drip for sedation Penicillin therapy was started It was found that more than 50% of the body surface had been destroyed The child was catheterized in order to control the output and intake of fluid It is suggested that over a period of 48 hours 100 cc of fluid is required for every 1% of body surface burned Thus the child required in the first 24 hours 2,400 ml plus 1,200 ml (insensible sweat loss) This was given in the ratio of 2 parts whole blood, 1 part plasma, and 1 part isotonic sodium chloride solution, the whole blood being given to replace corpuscles damaged in the full thickness burns Not until 7 days after admission did the child's general condition warrant toilet of the burns under general anesthesia Premedication consisted of 25 mg of chlorpromazine and 90 mg of pentobarbital, atropine being omitted on account of severe tachycardia Induction was commenced with cyclopropane and oxygen and when the child was asleep a vein was sought, and 20 mg of suxamethonium was injected Anesthesia was maintained, using circle absorption, with cyclopropane and oxygen Three weeks later, using the same routine, toilet and debridement of the burns, followed by application of homografts, were carried out Subsequently the patient's burns were dressed weekly under light cyclopropane anesthesia After the application of donor grafts from the mother, the patient was anesthetized about twice a week In the course of 6 months she was anesthetized 34 times for dressing and skin grafting

Small children generally dread anesthetics, and it often proves difficult for the anesthetist to retain the child's confidence if dozens of anesthetic procedures are required The author agrees with Shannon that it is impossible to dogmatize about the best anesthetic in a severely burned child A high concentration of oxygen is necessary to satisfy the metabolic demands of the child Rapid recovery is essential to allow resumption of a full dietetic regimen Cyclopropane is well suited for use in severely burned children, because it can be given with high concentrations of oxygen Control of the depth of anesthesia is easier by inhalation method, as venepuncture may not be feasible Cyclopropane is excreted unchanged from the body, and recovery is rapid

Chlorpromazine as an Adjuvant in the Relief of Chronic Pain J W Dundee Brit J Anæsth 29 28-34 (Jan) 1957 [Altrincham, England]

This report deals with the use of chlorpromazine as an adjuvant in the relief of pain and analyzes in detail the results obtained in 76 patients treated over a period of 30 months Very good results were obtained in subjects with malignant disease but poorer results in those with other types of pain These findings were similar to those obtained in 48 similar patients in whom the effects of chlorpromazine treatment were assessed by other practitioners Best results were obtained with a combination of chlorpromazine and levorphan Side effects occurred in 67% of the patients but necessitated stopping the chlorpromazine in only 2 The occurrence of an influenza-like attack, followed by jaundice was the most serious complication encountered in this study It is suggested that serum bilirubin and alkaline phosphatase determinations and leukocyte counts be made at frequent intervals in patients who receive prolonged treatment with chlorpromazine The dangers associated with the use of chlorpromazine do not appear to be sufficiently great to preclude its use in patients suffering pain due to malignant disease In other conditions one must assess whether the benefits likely to be obtained from the use of chlorpromazine are such as to outweigh the side effects associated with its use

Noradrenaline in Shock Due to Visceral Perforation D D Davies Brit M J 1 261-265 (Feb 2) 1957 [London]

Davies reports on 3 patients, a 66-year-old woman and a 49 year-old man with rupture of the sigmoid colon and a 75-year-old man with a large pyloric ulcer that had perforated, in whom shock was associated with the visceral perforation The patients were operated on and responded only temporarily to the infusion of moderate amounts of blood and dextran The systolic blood pressure level had dropped to 80, 70, and 75 mm Hg respectively, and, in order to raise it, the patients were given norepinephrine intravenously at the conclusion of the operation The strength of the infusion used varied from 4 mg per 1,000 cc of dextrose sodium chloride solution to 32 mg per 1,000 cc The rate varied from 10 to 80 drops per minute Intravenous administration of norepinephrine quickly raised the blood pressure levels, and, by a regulation of the rates of infusion, these levels were maintained fairly constantly The 2 patients with perforation of the large intestine recovered completely The patient with perforating peptic ulcer made a good immediate recovery but died 12 days later of a pulmonary embolus

It is suggested that, in patients with shock caused y visceral perforation, traditional methods of reuscitation should be tried first, but if these methods ail the use of a continuous norepinephrine infusion hould not be delayed Norepinephrine therapy is far rom being the complete answer to the problem of hock caused by visceral perforation, but its early use n the state of shock probably produces an increase in lood flow to vital organs This and the correction of nyocardial ischemia (after the increase in coronary lood flow) may be important factors in helping to revent the development of an irreversible phase that s refractory to treatment and for which norepinephine therapy is of no avail and may do more harm han good The importance of adequate oxygenation n the patient in shock is stressed

PHYSIOLOGY

Manual Artificial Respiration in the Sitting Posture H Ruben Lancet 1 134-135 (Jan 19) 1957 [London]

If a patient stops breathing while sitting in a dentist's chair, it is necessary to move the patient from the chair to the floor to apply any of the current methods of artificial respiration This wastes valuable time A new method of manual artificial respiration has therefore been devised for treating patients with apnea in the sitting posture Both inspiration and expiration are produced by this method by the operator stationed either in front of or beside the patient The patient s body is flexed in such a way as to bring the head and trunk close to the legs The flexion is increased by pressing on the patient's back This maneuver both compresses the abdominal contents, thus forcing the diaphragm upwards, and decreases the capacity of the thorax When the operator stops pressing on the back, the thorax will expand passively and reach its resting position, in which inspiration starts Inspiration is then increased by lifting the upper part of the body, thereby decompressing the abdominal contents and allowing the diaphragm to descend Artificial expiration and inspiration are applied alternately about 12 to 15 times a minute Experimental trials on curarized patients showed that an effective exchange of air was produced by this method The patient s position during the application of the method maintains a free airway and avoids aspiration

Oral Sodium Loading in Normal Individuals K Markley, M Bocanegra, G Morales and M Chiappori J Clin Invest 36 303-308 (Feb) 1957 [New York]

Sixteen healthy Peruvians between the ages of 20 and 28 years were placed in a recumbent position and given a quantity of isotonic sodium chloride solution equivalent to 10% of body weight by constant drip, with the aid of a stomach tube over a period of 21 hours Renal hemodynamics and electrolyte excretion were studied in 12 of the 16 subjects, and plasma volumes were studied in 7 of the 12 and in the 4 subjects before and after giving the sodium load The glomerular filtration rate increased by 32% after the administration of the sodium load as compared to the control value The effective renal plasma flow did not change significantly While the body weight was increased significantly at the termination of the loading with sodium, plasma volume did not change significantly The increase in body weight largely disappeared within 3 hours after the termination of the loading with sodium

While the sodium load was being given, 58% of the administered sodium and 51% of the administered water were excreted by the kidneys The concentration and total quantity of sodium excreted in the urine increased significantly at the termination of the loading with sodium An increased filtration of sodium by the glomeruli as well as a decreased reabsorption of sodium by the tubules are considered to be responsible for this phenomenon Water excretion also was increased, and its significance was masked by the slight water diuresis in the course of the control period during which a small quantity of water was given The diurnal variations of sodium and water excretion that occur without loading with sodium were evident also in the course of the loading with sodium but at higher levels than those reported under normal circumstances Total excretion of potassium as well as potassium concentration in the urine decreased after loading with sodium There were no important changes in plasma concentrations of red blood cells, total proteins or electrolytes

Respiratory Adaptations to Chronic High Altitude Hypoxia H Chiodi J Appl Physiol 10 88-92 (Jan) 1957 [Washington, D C]

Acclimatization to chronic hypoxia of high altitudes was studied in a group of men residing continuously for many years at 3,990 m (11,870 ft) and 4,515 m (13,545 ft) above sea level and in a group of lowlanders within 8 weeks of their arrival at these altitudes Resting pulmonary ventilation increased in the newcomers from the first hours of arrival at high altitude It reached its maximum level after 2 or 3 weeks and fell to a lower level after a certain time, but it did not return to sea-level values Changes in alveolar pCO_2, alveolar ventilation and oxygen ventilatory equivalent were in accordance with those of total ventilation Hyperventilation in the newcomers was greater than in the long-term residents Pure oxygen breathing at high altitudes depressed the average pulmonary ventilation more in the newcomers than in the residents but not to sea-level values The respiratory response to inhaled CO_2 in the newcomers at 11,870 ft was greater than that found in persons at sea level The response was equal or somewhat less in the long-term residents at 11,870 and 13,545 ft than in persons at sea level The mean arterial pH values of both groups at both altitudes were within the range found as normal at sea level No change in plasma proteins with regard to the sea-level values was observed

BOOK REVIEWS

Pediatric Cardiology By Alexander S Nadas, M D , F A A P , Assistant Clinical Professor of Pediatrics, Harvard Medical School Boston Cloth $12 Pp 587, with 343 illustrations W B Saunders Company, 218 W Washington Sq , Philadelphia 5, 7 Grape St Shaftesbury Ave , London W C 2, England, 1957

A vast amount of useful information concerning all types of heart disease, acquired and congenital, encountered in infants and children has been put in this relatively small volume This is derived from personal and published sources The first part of the book outlines the methods used in diagnosis, ranging from the initial history and physical examination to the newer techniques including phonocardiography, cardiac catheterization, and angiocardiography A brief outline of the theoretical principles involved introduces each diagnostic tool The data contained should be of practical value as standards by which to evaluate observations made on children The second part deals with acquired heart disease, including acute rheumatic fever and rheumatic heart disease The inclusion of aberrant origin of the coronary artery and endocardial fibroelastosis under this heading may be readily accepted, though it is somewhat illogical The third part, occupying about half the book, deals with congenital heart disease This is perhaps the best section of the book Clinical entities are grouped into broad classifications, departing from the usual groupings

As stated in the introduction, a personal stamp has been put on the entire book The book in a sense is a distillation of the author s extensive experience and a summary of his case material Emphasis is placed at all times on the practical approach to the diagnosis and treatment of heart disease rather than on a comprehensive coverage of details Dogmatic pronouncements, which deviate from views held by other cardiologists, are encountered at times For example, the belief is expressed that early and prolonged treatment of acute rheumatic fever with large doses of hormones will prevent valvular damage This is carefully labeled as a personal belief and evidence from the literature which contradicts it is cited Similarly, there are numerous statements that an experienced cardiologist might wish to challenge This does not, however, detract from the value of the book for those not primarily cardiologists, nor for the cardiologist, who can also profit from the author s wide experience This volume is highly recommended as an excellent introduction to pediatric cardiology

Handbook of Pediatric Medical Emergencies By Adolph G DeSanctis, M D , Professor of Pediatrics and Chairman of Department of Pediatrics, Post-Graduate Medical School, New York University-Bellevue Medical Center, New York With collaboration of Charles Varga, M D , and 10 contributors Second edition Cloth $6 25 Pp 389, with 73 illustrations C V Mosby Company, 3207 Washington Blvd , St Louis 3, 1956

This new edition has additional chapters on metabolic emergencies, accident and poison prevention, genitourinary emergencies, and respiratory paralysis in poliomyelitis Since the text, including the index, of this book contains only 389 pages, it is a handy and quick reference book for the busy pediatrician There are many instructive and self-explanatory illustrations This book is concise and to the point, and it should make an excellent addition to the library of the pediatrician as well as the general practitioner

Radiology of the Heart and Great Vessels By Robert N Cooley, M D , Professor and Chairman of Department of Radiology, University of Texas, Medical Branch, Galveston, and Robert D Sloan, M D , Professor and Director of Department of Radiology, University of Mississippi Medical Center, Jackson [These *pages are reprinting of Chapter IV, from 3-volume loose leaf* edition of Golden Diagnostic Roentgenology, with same page numbers used in that text] Cloth $12 Pp 4 1-4 309, with 195 illustrations Williams & Wilkins Company, Mount Royal and Guilford Aves , Baltimore 2, 1956

Two radiologists have contributed a superb and timely volume to roentgenologic literature The material embraces the mass of knowledge that has accumulated over the last 15 years It is presented with the day-to-day practice of this specialty in mind Procedures are outlined and discussed The normal appearance of the heart and great vessels is subjected to close scrutiny Mensuration is critically reviewed Pathological conditions, both usual and unusual, are considered Congenital malformations are classified and correlated with disturbed function The role of the radiologist in diagnosis, although admittedly subject to flux, is delineated Particular attention is given to those conditions that are amenable to correction The printing is excellent Numerous illustrations are ably done and well grouped A well chosen up-to-date bibliography is included This volume is highly recommended to the radiologist as well as to those who are engaged in roentgenology of the heart and great vessels

QUERIES AND MINOR NOTES

DIAGNOSIS AND TREATMENT OF PERNICIOUS ANEMIA

To the Editor —*Can vitamin B$_{12}$, when used in the treatment of pernicious anemia, be given subcutaneously, in the same dosage, and with equally good results as when given intramuscularly? Since it is rapidly excreted when given intramuscularly, would not better results be obtained with smaller doses taken more frequently? Patients could be trained to take it subcutaneously, as diabetics take insulin The statement is often made that true pernicious anemia does not exist, if there is free hydrochloric acid, and that treatment should not be started until a positive diagnosis has been made Has anyone ever made an estimate of the number of patients who have been treated for pernicious anemia, especially in rural districts, who have never been given a gastric test? Do not many physicians treat patients with typical symptoms and blood findings at once and then, if there is rapid and excellent response to treatment, give a diagnosis of pernicious anemia and continue treatment without confirming the diagnosis by gastric tests for hydrochloric acid?*

M D , Connecticut

Answer —Vitamin B$_{12}$ may be administered subcutaneously as well as intramuscularly, injections cause little irritation, and the therapeutic effects are comparable While it is true that with large doses of vitamin B$_{12}$ the excess is rapidly excreted, there is fair retention when doses of moderate size are employed Fifty micrograms injected once every four weeks constitutes a satisfactory maintenance schedule and gives fairly normal blood levels of vitamin B$_{12}$ even at the end of the four-week period No one has been able to obtain evidence that more frequent injections offer any advantage Patients may be trained to administer the vitamin B$_{12}$ themselves, but even so they should be seen at regular intervals by their physician and care should be taken to make certain that a preparation of known potency is being used If a diabetic patient fails to take his insulin, he usually finds himself in trouble within a short period The patient with pernicious anemia, on the other hand, who becomes careless about his injections may get along reasonably well for months to a year or more before he becomes anemic or develops progression of the neurological lesions of the disease A trip to a physician's office once every four weeks for observation and for the vitamin B$_{12}$ injection is the best way to provide maximum assurance of optimum therapy

Unfortunately, it is true that many physicians treat patients for pernicious anemia without establishing the presence of achlorhydria or without following the therapeutic response carefully Often, too, they will give transfusions and iron therapy at the same time One then is faced with the problem of not having established the diagnosis and of not knowing whether treatment should be continued for the lifetime of the patient If a gastric analysis is then done and free hydrochloric acid is found, one can essentially eliminate a diagnosis of pernicious anemia If achlorhydria is found, however, the problem is more difficult, and one would have to measure the absorption of orally administered, radioactive-cobalt-tagged vitamin B$_{12}$ in order to be sure

PERIODIC FEVER OF 10 YEARS' DURATION

To the Editor —*For the last 10 years a 48-year-old man has had weekly elevations of temperature up to 102 or 103 F (38 9 or 39 5 C), occasionally preceded by a rigor After about four or five hours, the temperature returns to normal, but occasionally the fever has lasted two days Except for body aching and generalized headache, there are no associated symptoms No relief is obtained from aspirin, and he usually does not stay away from work because of the fever The onset occurred when he had a "stomach ache," 11 years ago, and at that time a duodenal ulcer was diagnosed by a gastrointestinal series His weight went from 160 to 130 lb (72 6 to 59 kg), and about a year later the elevated temperatures became prominent Exhaustive tests have been conducted, including all sorts of viral studies, agglutination tests, fungus studies, bone marrow, skin, and muscle biopsies, stool examination, intravenous pyelography, study of the gallbladder, gastrointestinal series, and barium enema, all with negative results His history reveals the usual childhood diseases, he had mumps at 37, no malaria, an appendectomy at 30, and a fractured collar bone at 27 He farmed until 1938, since then he has been employed in school maintenance He has used pasteurized milk since 1939 His family history is noncontributive Physical examination is negative except for moderate tension and nervousness He was treated once for brucellosis (undulant fever), with no relief He has been given Equanil and Frenquel, Dilantin (in case the condition is some manifestation of epilepsy), and steroids, with no improvement The fever really seems to be psychogenic Please provide some help in this case*

M D , Texas

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —The first point to establish in any mysterious febrile illness is that the fever is genuine Occasionally persons with peculiar mental quirks find solace in inventing a fever, and they may go to remarkable lengths in cleverness and cunning, passing off as real a spurious fever The tricks are legion, and their detection is not simple If the episodes of fever are real, in the light of all the negative evidence this man un-

---

The answers here published have been prepared by competent authorities They do not, however represent the opinions of any medical or other organization unless specifically so stated in the reply Anonymous communications and queries on postal cards cannot be answered Every letter must contain the writer s name and address but these will be omitted on request doubtedly has what Reimann calls periodic disease. Under this heading he has described an assortment of disorders of unknown cause that have in common regularly recurring short episodes of disease; these may occur intermittently for many years without affecting the general health. Mysteriously repeated episodes of fever, which commonly occur at intervals of about a month rather than a week, constitute one large group of the cases he has gathered. Symptomatic relief may ordinarily be obtained with salicylate compounds in some patients; steroid hormones are usually less successful. The nature of the strange, mysterious tides of this inherent rhythmicity are as obscure as the treatment is unsatisfactory. However, in spite of the distress it causes, the disorder seems to be surprisingly benign in terms of threat to general health or life.

Answer.—The circumstances portray the usual dilemma physicians face when they encounter one of the periodic diseases, in this case almost certainly periodic fever. Many victims, in addition to the necessary exhaustive studies mentioned, also have been deprived of their tonsils or teeth in a search for "focal infection" and have received a battery of antimicrobials, all to no avail. Brucellosis, epilepsy, psychoneurosis, malaria, Hodgkin's disease, tuberculosis, and other chronic ailments usually are suspected. It is surprising that so typical a case could not be diagnosed, considering the numerous reports on the subject in the literature. The cause is unknown, and there is no effective treatment. The episodes may persist for life, but in some instances the symptoms diminish and the intervals lengthen over the years. In a few persons they disappear. Most victims learn to live with their discomfort, and some obtain relief with aspirin, barbiturates, or alcohol during the episodes. Adrenal steroids have given temporary relief in some patients with periodic peritonitis, but if the patient in question actually had a duodenal ulcer 11 years ago they may cause a recurrence. An explanation of the disorder and reassurance are the best one can offer a victim at present. The subject is discussed in detail by Reimann (*Medicine* 30:219, 1951.)

AUTOCLAVING OF SPINAL ANESTHETICS

To the Editor:—*How often, if at all, can spinal anesthetic agents such as Pontocaine, procaine, 6% dextrose solution, and epinephrine be autoclaved?*

Fred B. Ely, M.D., Orland, Calif.

Answer.—Pontocaine and procaine, in a study carried out by Carter and associates (*Anesthesiology* 15:480, 1954), were autoclaved at 250 F five consecutive times and then were subjected to chemical tests by the manufacturer and were also used for anesthesia. There was no detectable loss of potency by either method of assay, and there was no increase in the percentage of complications following the use of these agents. Solutions containing dextrose should not be reautoclaved, as this may result in caramelization, which may give rise to irritating breakdown products. Repeated autoclaving of epinephrine may lead to partial destruction of this agent, with loss of potency, so that it should probably not be subjected to more than one autoclaving. Ampuls can be autoclaved with little waste by placing the two or three ampuls required for the induction of each type of spinal anesthesia in a large test tube for autoclaving. It is thus possible to select exactly the combination of drugs needed for the induction of each type of anesthesia so that it is not necessary to discard or reautoclave unused ampuls.

SATURATED FATS IN COTTAGE CHEESE AND CREAM

To the Editor:—*Please enlarge upon the subject of the percentage of saturated fats contained in cottage cheese and cream mentioned in Queries and Minor Notes under Arteriosclerosis and Diet in* The Journal *for Nov. 17, 1956, page 1200.*

Augustin Jones, M.D., St. Louis.

Answer.—Uncreamed cottage cheese contains only 0.5% total fat, and the amount of saturated fats present in creamed cottage cheese depends entirely upon the amount of cream added to the cheese. The saturated fats in light cream (20% butterfat) amount to about 11%, so if one were to use cottage cheese containing light cream in the amount of 10%, the amount of saturated fats in the cheese would be slightly over 1%. The reply to the query mentioned refers to a specific dietary problem, and the answer should not be applied to the diet in general; there should be no implication that the ingestion of saturated fats in cottage cheese or any other wholesome food is undesirable.

DECREASED INSULIN REQUIREMENT

To the Editor:—*For a period of about 20 years a 73-year-old man administered 20-30 units of insulin to himself daily for diabetes mellitus. Without insulin he showed (4+) urine sugar. Nine months ago, after a stroke that resulted in a hemiplegia, it was found that he no longer needed insulin, as evidenced by absence of sugar in the urine and normal blood sugar concentration. To what process can the sudden disappearance of the diabetes mellitus be attributed?*

M.D., North Carolina.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—Many patients as they grow older require less insulin, particularly if the diabetes is mild, as in this case, as evidenced by the 20 years' duration of the disease and the moderate amount of insulin necessary to control it. In the present case, it would seem likely that after the "stroke" the diet was so carefully selected and was so restricted that the patient's urine became sugar free and the blood sugar level normal. It is a quite common experience for even younger patients taking more units of insulin to have their urine become sugar free when they are admitted to a hospital and placed under close supervision.

Answer.—Without much doubt the patient is still diabetic, as a glucose-tolerance test would show, even though he seems to have lost the symptoms of diabetes. There is nothing about hemiplegia or the cerebral damage producing it that would be expected to ameliorate the diabetic state. It is probably a safe assumption that the improvement noted is due to a considerably diminished food intake This course of events is not unusual in older patients whose appetites fail after a severe illness

LEAD AND ANTIMONY TOXICITY

To the Editor —*Is there any information regarding lead or antimony poisoning in printers or linotype operators having cutaneous contact with lead type? No history of oral contact with type was established If so, what symptoms or tests could be performed to determine antimony poisoning?*

M D, North Dakota

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —Lead poisoning, as well as antimony poisoning, does not occur as a consequence of absorption of the metal or its inorganic compounds, including the oxides, through the skin Some absorption may occur as the result of putting the fingers, or food or other articles so handled, in the mouth, but this, except through the most flagrant violation of ordinary measures of cleanliness, is insufficient to cause poisoning Poisoning usually occurs, if at all, and very rarely, among printers when fumes from the molten alloy and dust from oxidized, spilled metal are dispersed into the atmosphere in the immediate vicinity of the printer in dangerous concentrations (above 0 15 or 0 20 mg per cubic meter) throughout the greater part of the hours of work

The detection of an abnormal or potentially dangerous degree of absorption of either lead or antimony can best be established by precise quantitative determination of the rate of the urinary excretion or the concentration of the metal in the whole blood The diagnosis of intoxication, when a potentially dangerous level of absorption has been demonstrated by analysis (or otherwise), must always depend upon the differential diagnosis of presenting symptoms and physical signs This consultant has never seen a case of antimony poisoning in a printer

Answer —Insofar as this query is predicated upon percutaneous absorption of lead or antimony, it may be denied that any such portal of entry exists in the trades mentioned Theoretically, no vapors of lead or antimony arise in connection with linotype operation because of the relatively low temperatures involved Practically, some lead and antimony oxide are produced, so that poisoning becomes a possibility, although a rarity Since the lead dominates the mixture, the initial diagnostic effort should center about that element As a preliminary step, the urine should be examined for porphyrins by the technique described by McCord (*Indust Med* 20 185, 1951) A positive test is not conclusive as to lead poisoning, but, if the test is positive, it might be followed by appropriate blood or urine quantitative examination For the blood, any quantity above 0 08 mg per 100 cc should be regarded as abnormal For the urine, any quantity in excess of 0 08 mg per liter should be regarded as significant While antimony poisoning is a possibility, it is so infrequent that chief activities should center about the possibilities of lead poisoning

HUMIDITY AND TUBERCULOSIS WARDS

To the Editor —*The following problem has arisen in the tuberculosis division of a large state mental hospital The basement of one of the buildings has been used for patients with quiescent and arrested cases of pulmonary tuberculosis until the disease becomes inactive, at which time such patients are transferred either to the general service in this hospital or back to the original state hospital from which they were transferred for treatment of their pulmonary condition Although considerable money has been spent on heating and ventilation in the basement of this building, it still seems too damp at certain periods of the year, especially during the summer months What are accepted satisfactory humidity readings and conditions for patients of this type?*

Paul C Burnett, M D, Logansport, Ind

Answer —The terms "quiescent" and "arrested' are no longer current in the classification of status of cases of tuberculosis If a presumably inactive case is meant, with the patient being held for a period of time to make sure of the status, it seems that the ward conditions could be the same as those in the general wards of a state mental hospital, with the addition, however, that the patient should be in quarters isolated from nontuberculous patients Unless humidity per se is excessive, it is not an important factor for tuberculous patients, and of course the wards should be kept warm

EFFECT OF CORTISONE ON THE BREAST

To the Editor —*Is there any report of disturbance in the breast occurring after the use of cortisone? A patient has congestion and pain in both breasts that developed after cortisone medication The patient is 54 years old and has not menstruated for four years She has never had any complaints regarding the breast before She states that, at the same time the breasts were sore, she had a white vaginal discharge No abnormality in the breasts could be found except for tenderness, and there was no secretion*

Rebecca McConnell, M D, Pittsburgh

This inquiry has been referred to three consultants, whose respective replies follow —Ed

Answer —According to the best knowledge available, disturbance of the breast is not one of the long list of side-effects known to have occurred during the use of cortisone However, amenorrhea has been described after use of anti-inflammatory agents, including hydrocortisone

Answer —Cortisone therapy suppresses adrenal function and reflexly suppresses pituitary function However, all hormones are suppressed about equally, and therefore there should be no disturbance in pituitary stimulation of the ovary to account for symptoms as described If cortisone therapy is to be blamed for the symptoms, it seems more likely that sodium retention would be the cause

ANSWER —The exact role of the adrenal cortex in breast development and function is a moot question The results of experimental work have been somewhat contradictory More recent evidence points to the fact that corticotropin (ACTH), cortisone, and hydrocortisone have an effect on breast development and on the pituitary prolactin content Cortisone has been found to produce branching of the ducts, lobule-alveolar development, and secretory activity in the mammary glands of mature female rats It also caused an increase in the pituitary prolactin content It appears to be necessary to have estrogen affecting the breasts as a preliminary to cortisone stimulation In the case reported, it is quite likely that the estrogen was from the adrenal gland since the patient had not menstruated for four years Although this is not a common experience, it is quite likely that cortisone can bring about so-called congestion of the breasts in a postmenopausal woman The pituitary-adrenal-ovarian axis may be involved in such a way as to increase the prolactin content of the pituitary sufficiently to bring about a certain amount of increase in vaginal secretion The dose and frequency of administration of the cortisone, which was not stated would be a factor

CHRONIC OSTEOMYELITIS WITH DRAINAGE

TO THE EDITOR —*A patient who has had osteomyelitis of the left tibia for 35 years now has some sinus drainage However, he is sensitive to penicillin, and the question comes up as to treatment of this type of condition with antibiotics Would it be desirable to culture the fluid from the sinus, do sensitivity tests for antibiotics, and start treatment with them, or have studies found this approach to be unsuccessful? Occasionally the patient gets a slight elevation of temperature that might possibly be due to the osteomyelitis, but this is of low grade and has not prevented him from working*

G L Lester, M D , Chautauqua, N Y

This inquiry has been referred to two consultants whose respective replies follow —ED

ANSWER —In this instance two questions should be answered before treatment is considered 1 Does this patient have a sequestrum in the tibia or a localized bone abscess without sequestration? 2 Is the drainage due to a squamous cell carcinoma arising in the lining of the sinus tract?

The first question can be answered by an x-ray examination with or without the injection of the sinus with a contrast medium, and the second question can be answered by biopsy It is entirely possible that the intermittent drainage is due not to actual bone involvement but rather to the flare-up of infection in the scar tissue of the area As in all infections, it is desirable to know the nature of the specific organism, but in chronic osteomyelitis with sinus formation the culture usually brings out a mixture of organisms rather than the pure strain that is usually cultured in the acute form of this disease One of the difficulties of antibiotic therapy in the management of chronic osteomyelitis is that the disease is usually walled off by sclerotic bone and heavy avascular fibrous tissue, so that, however adequate the blood level of the antibiotic, there is no assurance that adequate amounts of the drug are reaching the causative bacteria

ANSWER —It is quite possible that a chronic osteomyelitis such as is mentioned can be cleared up with proper antibiotic therapy and, later, surgery Many cases that have been present for years have been at least fairly permanently arrested by this type of treatment Certainly, specimens from the depths of the wound should be cultured and sensitivity tests run on the organisms before any antibiotic therapy is begun, and usually it is best to use this in conjunction with adequate surgery

BLOOD PLATELET COUNTING

TO THE EDITOR —*I would like to comment on the statement that 'an enumeration of platelets by any method is at best an approximation," which appeared in the query about blood platelet counting in* THE JOURNAL, *Jan 26, 1957, page 327 With the method that I have outlined in my monograph "Physiology and Pathology of Hemostasis" (Philadelphia, Lea & Febiger, 1951, p 112), the platelets can be counted with the same precision as the erythrocytes because the adhesiveness and clumping of the cells are prevented Unfortunately, in many clinical laboratories platelets are not counted directly in a counting chamber but in a stained smear, and for such a procedure the comment that it is "at best an approximation is fully justified*

Armand J Quick, M D
Department of Biochemistry
Marquette University School of Medicine
Milwaukee 3

The above comment was referred to the consultant who answered the original query, and his reply follows —ED

TO THE EDITOR —*Everyone who devises a new method for counting platelets believes that he has overcome the deficiencies of the previous ones The very multiplicity of methods and the frequency with which new ones appear belie this, as do the experiences of many workers who use one or another method routinely The marked variability of repeated counts on the same withdrawn blood specimen and of consecutive counts made on the same individual is well known (Brecher and others* Am J Clin Path 23 15, *1953)*

The correspondent has described a direct method combining techniques previously used, namely, using siliconed glassware, cooling the specimen in ice water, diluting with the Rees-Ecker solution, and counting in a blood cell counting chamber It is better than some methods, but it is far from ideal The correspondent is of the opinion that the adhesiveness and agglutination of thrombocytes are due to thrombin formation, while most investigators believe that these are inherent properties by virtue of which platelets initiate and enhance the clotting process but which, at the same time, make them unamenable to accurate enumeration

New Doctor Procurement Bill on Way Through Congress • •

Schools Want Higher Research Allowance for Overhead • •

Dr. Reuling on Delegation to WHO Meeting in Geneva • •

Congress Studying Dangers in Radioactive Fall-Out • •

HEARINGS ON NEW DOCTOR PROCUREMENT PROGRAM

Any new legislation for the special procurement of doctors should also continue the Medical Advisory Committees to the Selective Service System, in the opinion of the American Medical Association. The Association's views were presented to the House Armed Services Committee by Dr. Harold S. Diehl, dean of medical sciences at the University of Minnesota and Chairman of the A. M. A.'s Council on National Defense. Dr. Hugh Hussey, an A. M. A. Trustee, introduced Dr. Diehl to the committee and assisted him in answering questions by the representatives.

Before the committee is a Defense Department bill that would amend the regular draft act when the special "doctor-draft" act expires next June 30. The bill would authorize the drafting of physicians as physicians, and not necessarily in the same age groups as other draft-eligible men.

Dr. Diehl strongly recommended that the national, state, and local committees be continued. "As on past occasions," he said, "that committee can be of great assistance in advising the Department of Defense and Selective Service System on matters pertaining to reserve officers and military medical affairs. Furthermore, in the event of need for an immediate increase in mobilization requirements, it would be costly and time-consuming to authorize and effectively activate another chain of advisory committees."

In 1950 the A. M. A. supported a form of the original "doctor-draft" act as necessary to bring about the orderly and equitable procurement of military physicians, and in 1953 supported a one-year extension of the act. However, the Association vigorously opposed further extensions as unnecessary, Dr. Diehl pointed out. He cited the following statement adopted by the A. M. A. Board of Trustees in April:

"The Board of Trustees of the American Medical Association recommends that the discriminatory and undemocratic legislation known as the doctor draft act be terminated at the present expiration date, June 30, 1957."

Dr. Diehl outlined the A. M. A.'s position as follows: "The Association believes that if the demands for the defense and security of our nation are such that, in the opinion of Congress, it is necessary to have a Universal Military Training and Service Act to maintain the strength of our armed forces, then one method to insure a sufficient supply of physicians for the armed services would be to enact legislation such as is proposed [by the Defense Department].

"We are of the opinion that physicians should be (1) registered and classified in the same manner as other citizens in the same age group, (2) deferred for educational purposes in the same manner as other registrants, and (3) called to active duty or inducted under the same general provisions as other registrants deferred for educational purposes.

"As we understand it, this bill provides for a selective call-up of physicians, up to age 35, who have not as yet fulfilled their military obligation under the provisions of the basic Universal Military Training and Service Act. Discrimination will result from the administrative method which will have to be instituted by the Selective Service System to segregate the names of those physicians registered under the regular draft. Such a temporary procedure may be necessary, but when it is no longer required, we believe that even this degree of discrimination should be eliminated."

After two days of hearings, the committee voted to report favorably a bill providing for the selective call-up of physicians, dentists, osteopaths, and allied health personnel, but not beyond age 35. The bill also would continue the national state and local advisory committees, as well as some of provisions of the original draft act that were designed to protect the rights of physicians.

At the same time the committee voted to place in its report on the bill a statement recommending that the ratio of physicians to troops be continued at 3 per 1,000. Chairman Vinson said it was intended to "alert the Appropriations Committee so the military won't get the money" to carry out a planned increase in the ratio of 3.4 per 1,000.

LARGER U. S. SHARE OF RESEARCH OVERHEAD URGED

Medical schools and other research institutions were pictured to a Senate appropriations subcommittee as struggling against "terrific fiscal odds" while at the same time engaged in "one of the greatest give-away programs of all times." The witness was Dr. Lowell T. Coggeshall, president-elect of the American Association of Medical Colleges and former special health assistant to Secretary Folsom.

Dr. Coggeshall explained that the "give-aways" referred to the additional overhead expenses schools incurred in doing research. Federal spending for all research in private institutions amounted to only 15 million dollars at the start of World War II, while the total now is in excess of 300 million, he said. "When a few projects were supported in an institution they could be absorbed with little or no additional cost on the part of the university, but since the programs have reached the size they now assume, the demand for accompanying dollars is so great that many institutions are becoming genuinely alarmed."

The witness was supporting the administration's plea for Congress to permit up to 25% additional for overhead costs in any government research grant in the health field. The House, in voting the Health, Education and Welfare budget for the next fiscal year, set a 15% ceiling, which Secretary Folsom and other government witnesses argued was too low and out of line with other federal agencies.

Dr. Coggeshall explained overhead or indirect costs as including administration, maintenance, library expense, utilities, and space renovation. He insisted his was not "a plea for a hidden subsidy or a request for the government to support medical education" but was

Washington News—Continued

a 'straightforward request for the Department of Health, Education, and Welfare to pay its legitimate share of the costs of medical research Otherwise our institutions will become still further impoverished as they make up their deficits from reserves or by diverting funds from other essential educational purposes

He also noted in passing that tuition had risen in medical schools by 84% since 1940 Chairman of the appropriations subcommittee is Senator Lister Hill (D, Ala), who is sponsoring a bill for federal construction aid to medical schools Senator Hill also is chairman of the Labor and Public Welfare Committee, which handles such legislation

In earlier testimony Dr James A Shannon, director of the National Institutes of Health, said that other agencies of government have been allowing considerable for overhead costs in research but that in the health field it had been held at 8% up until 1954 The 15% figure since then, he added, is imposing a serious drain on operating funds, "which are at a critical point'

In other committee developments, the American Dental Association asked for funds to complete the National Dental Institute building at the National Institutes of Health and to increase research grants by 1 million dollars Other organizations testifying in support of more federal support for medical and allied research included the American Nurses Association, the National Paraplegia Foundation, the National Education Association, and the National Association for Retarded Children

WORLD HEALTH ASSEMBLY MEETING

The United States delegation to the World Health Assembly now under way at Geneva is made up of three physicians, including Dr James R Reuling, a Trustee of the American Medical Association Others are Dr Leroy E Burney, surgeon general of the Public Health Service, and Dr H van Zile Hyde, chief of the PHS division of International Health Alternate delegates are Dr Aims C McGuiness, special assistant for health to Secretary Folsom, and Howard B Calderwood, Ph D, of the State Department

Congressional advisers to the delegation are Representatives John Fogarty (D, R I) and Charles Wolverton (R, N J) Other advisers include Drs Lester W Burget, dean of the dental school, University of Pennsylvania, Eugene P Campbell, International Cooperation Administration, Edwin L Crosby, executive director, American Hospital Association, Franklin D Yoder, president, State and Territorial Health Officers, and Richard C K Lee, Honolulu Board of Health The Health Assembly meets annually as the supreme authority for the World Health Organization Its role includes review of the WHO budget and programs

CONGRESS TO STUDY RADIOACTIVE FALL OUT

Congress will look into the problem of radioactive fall-out from nuclear weapon explosions The Joint Committee on Atomic Energy has named a special subcommittee to investigate the situation, with Rep Chet Holifield (D, Calif) as chairman Mr Holifield headed a House government operations subcommittee that made an extensive study last session of the civil defense setup

The radiation hearings, set for May 27 through June 7, will study such things as how much radioactive debris is being scattered in the atmosphere by nuclear weapons, the genetic effects of radiation, and the relationship of the body's intake of strontium 90 to bone cancer and leukemia Following discussion of these matters, an attempt will be made to project the effects of continued testing of weapons, the committee said

Mr Holifield commented One of the major problems in previous discussions has been that the Congress and the public had been snowed under by a welter of uncoordinated information and scientific terminology without having an adequate frame of reference for their guidance Chief purpose of the hearings is to provide such a frame of reference through presentation of scientific information in a form which is readily understandable to the layman as well as the scientist'

The hearings, he said, should provide background information for the committee, which is planning separate hearings on radiation injuries to workers and on workmen's compensation in this field

RESEARCH IN VETERANS ADMINISTRATION

Latest reports on medical research in the Veterans Administration show about 4,000 active projects under way, a forty-fold increase in the last 11 years During the same period, the VA researchers published papers increased from approximately 20 to more than 900

Discussing research, the report states

There are today, in the Department of Medicine and Surgery, resources of intellect, ability, and imagination which make the agency an important contributor not only to the health of veterans, but also to the advancement of medical knowledge for the benefit of the entire country

This has come about, in no small measure, as the result of the substantial assistance of the medical schools and the efforts of large numbers of the medical profession in the United States serving in advisory, consultant, and training capacities'

The VA's medical research has been largely conducted on a decentralized basis, with interns, residents, and junior staff members as well as senior members encouraged to suggest projects The suggestions are evaluated first by a hospital research committee, then by the dean's committee, if there is an affiliated medical school

Among future studies expected to be undertaken are evaluation of early diagnostic and treatment measures for glaucoma, evaluation of treatment measures for Parkinson s disease, a cooperative investigation of treatment measures for diseases of the adrenals and other endocrine glands, studies in treatment and rehabilitation of patients with aphasia and therapies for epilepsy, and studies of the blood of patients with heredity diseases of the nervous system

NAVY COMMISSIONS AVIATION MEDICAL CENTER

The Naval Aviation Medical Center at Pensacola, Fla, has been formally commissioned, with Capt Lester E McDonald as commanding officer The center brings in these activities Naval School of Aviation Medicine, the Naval Hospital, and certain parts of the Naval Dispensary

According to Navy Surgeon General Hogan, establishment of the center will make it possible to provide for more effective and economical integration of existing medical department facilities and personnel It also will extend "the scope and improve the quality of educational, clinical and research aspects of aviation medicine, which is necessary to meet the ever increasing demands imposed on today s aviation and future naval aviation

(cont d)

'LANOXIN' continues to offer the same advantages — only the name has been changed.

The full effects of each dose develop quickly to permit rapid appraisal of the need for additional drug. Moreover, the limits of the patient's therapeutic range, which may be reduced in the seriously ill, may be approached with relative safety because toxicity, if it develops, soon abates. For true balance and uniformity of therapeutic effect, prescribe 'LANOXIN' brand Digoxin.

Sincerely,

'B W & Co'

IMPORTANT NEWS FROM BAUER & BLACK

Famous GYPSONA* Plaster Bandages now brought to you by CURITY

Gypsona's special interlocked woven fabric and special plaster of Paris makes accurate moulding easy Gypsona wets in seconds, sets in 4-5 minutes

Gypsona's white, porcelain-like surface stays neat and clean even after weeks of wear And Gypsona casts are lightweight yet extremely strong

Now you get the advantage of Curity servicing for the plaster bandage made of special imported plaster of Paris

This world-famous quality product does not use ordinary plaster of Paris Gypsona is made of pure white, creamy, finely ground plaster from a special quarry in England

Wound on a plastic core, Gypsona unwinds easily and will not "telescope"

Gypsona wets in seconds, with virtually no plaster loss And because of its high plaster content (90% by weight) you get lightweight casts that are really *strong*—maximum functional treatment (And, of course, you use less, too)

No wonder so many specialists and orthopedic surgeons throughout the world insist on Gypsona Available now from your Curity representative

The Lore of Stones and Medicine

The lore of stones is multitudinous and of great interest Apart from providing the instruments and weapons of our 'lithic ancestors, this material has always been endowed with magical properties, and the fact that it could descend from heaven (in the form of meteorites) invested it with special sanctity Flints and arrowheads of the Stone Age were later looked upon as elfin arrows which could kill cattle by penetration of the hide with insignificant entrance wounds The sudden stab of pain which signalled an attack of lumbago was thought to be an elf shot, which was cured by boiling a stone arrowhead and drinking the water In Ireland the mitre stone of a high cross is still placed on the head to cure headache Healing stones are common all over Europe After devotional preliminaries the suppliant passes the stone round his body sun-wise It is said that passage in the reverse direction invokes a curse on one s enemies Healing stones are reputed to have the miraculous property of returning to their normal resting-place Some have been stolen, thrown into the ocean or carried to sufferers too ill to make the pilgrimage but they always return Stones for curing backache are very common, like the crickstone at Morna Cornwall and at the Church of the Holy Sepulchre in Jerusalem The water which collects in basin stones is reputed curative of warts, skin and eye diseases at some a pin thrown into the water reinforces the cure Other stones credited with healing virtues are organic concretions and various precious stones Adder stone (coralline limestone) was reputed effective against snake-bite, and the mythical toad stone against furies and all calamities The savage medicine-man carries as equipment stones—renal gall, or even small pebbles Bezoar (gall stones or enteroliths) was popular in the sixteenth and seventeenth centuries for prevention of plague and poisoning These were scarce expensive and frequently faked Lithontriptics were stones used to dissolve stones in the homeopathic mode, for example, grit from a cock s crop was powdered and drunk in water to dissolve bladder stone In 1739 Mrs Joanna Stevens received by Act of Parliament £5,000 for the recipe of her stone remedy, which consisted of calcined egg shell, snails, pigs droppings soap, burdock hips and haws

Amulets can be of any material—wood, mineral, hair, amber crystal or precious stones gems and jewels have a magical lore of their own Amber beads were worn to prevent plague and in Ireland cataract is relieved by rubbing the eyes with the tenth bead of a rosary Blood stones and red coral were given (powdered) for hæmorrhage—a homeopathic remedy Coral was also hung round infants necks as protection against fits and sorcery and many old types of children s rattle have a stem of this material Coral changed colour in the presence of poison which made it a prized possession and heirloom in the Middle Ages It changed colour also according to the state of health of the wearer, a property shared by the turquoise, opal and pearl The amethyst (from the Greek not drunk) rendered its wearer proof against inebriation Amulets were safeguards from the accidents of life, from evil machinations, or to promote health, wealth and prosperity Personal amulets were worn next the skin, household ones (e g , horseshoes) fixed to the door Early in the present century all chemists stocked camphor moulded in the shape of a Maltese cross, which was worn as a preventive of infection and iodine lockets as charms or cure for everything went into the limbo not very many years ago People have been known to carry a potato as a charm against rheumatism Some previous or semi-previous stones cut and mounted in gold or silver and often carved with cabalistic symbols have become famous as healers —T H Crozier, M D , Folklore and Medicine, *The Ulster Medical Journal,* Nov 1, 1956

Galen

When Galen began his studies of anatomy and physiology, medicine was almost entirely innocent of a scientific basis Hippocrates initiation of rational medicine had been a tour de force founded only on shrewd observation, and the lesser men who followed him in the 500 years before Galen were split into squabbling sects Galen 'set out to develop systematic descriptions of the human body He was handicapped by the fact that it was forbidden to dissect the dead The only part of human anatomy that he could investigate in toto was the skeleton, which he often did where tombs or monuments have been broken up For the rest he relied on dissections of animals, including monkeys, and on examinations of tissues exposed in patients with disease or wounds While he was studying with Satyrus at Pergamon there was an epidemic of carbuncle (probably anthrax) which destroyed areas of skin and flesh in many of the victims Galen wrote later Those of us who had seen Satyrus dissecting any of the denuded parts, easily recognized them and made a complete diagnosis, telling the patients to make some movement which we knew to be carried out by such and such a muscle, and sometimes diverting or drawing aside the muscles to observe an adjacent large artery, nerve or vein We saw that all the other physicians were like blind men without any knowledge of the parts exposed

Galen was the first to demonstrate that muscle has but one action—contraction He proved by experiments that the movement of a muscle during its relaxation was produced by the contraction of an opposing muscle He went on to establish that each muscle has only one direction of contraction Attempting to discover what force caused muscles to contract, Galen came to the conclusion that the force originated in the brain and was communicated to the various muscles by the nerves He arrived at this idea as a result of a wonderful series of experiments on the nervous system, particularly the spinal cord Operating on experimental animals, he systematically cut the cord at one vertebra after the other down the backbone He found that when he severed the cord between the first and second vertebrae in the neck, the animal instantly stopped breathing and died Further down, the animal survived and retained certain functions When he cut the cord between the sixth and seventh vertebrae, for instance, the chest muscles were paralyzed but the animal was able to breathe by means of its diaphragm When he cut below the eight vertebra, the arms escaped paralysis He also observed that when the cord was cut only half way through only one side of the body was paralyzed In this way Galen mapped the control areas of the cord In addition he investigated various peripheral nerves and established that in general the interruption of a nerve caused loss of motion and sensation below the block but not in the part of the body between it and the brain Galen's general concept of the body s physiology comes reasonably close to modern ideas If we substitute oxygen for vital spirit,' and nerve electrical potential for "animal spirit, the system begins to approach a 20th century description —F G Kilgour, Galen, *Scientific American,* March, 1957

REHABILITATION OF THE CARDIAC PATIENT

Herman K. Hellerstein, M.D.
and
Amasa B. Ford, M.D., Cleveland

• *The process of rehabilitation begins at the moment the patient is first stricken with his disease. The goal is the maximal attainment within the patient's capacities. In approximately 80% of cardiac patients the total program can be managed by the private physician; in others, a team approach and help from specialists is necessary. It is assumed that adequate attention has been given to medical therapy, rest, relief of pain, oxygen requirements, nutrition and sedation. In addition, the patient's emotional problems must be dealt with. The period of passivity which is frequently required at first should be terminated as soon as possible. The periods of hospitalization and of convalescence at home are followed by a period of vocational readjustment, and each presents problems that can be solved on the basis of available facts. There has been no evidence that employment has aggravated the underlying disease in cardiac patients, and there have been no medicolegal compensation cases involved in the employment of such patients.*

This report describes an orderly plan for the rehabilitation of the patient with heart disease from the initial illness through convalescence to the return to the world of work. Although many disciplines (medical, psychiatric, vocational, social service, occupational therapy, and physical therapy) may be employed, the physician is the guiding force and cohesive influence throughout the total illness and treatment. We assume that treatment of the cardiac patient is directed to the whole patient and to the total illness.

The physician's responsibility is for the comprehensive management of the patient, that is, diagnosis, medical or surgical care, convalescence, rehabilitation, and work prescription. Each phase of care must enjoy the same status as that of the so-called scientific aspects of diagnosis and treatment. The practice of rehabilitation should not be below the dignity of the physician. He should derive as much satisfaction from helping an incontinent hemiplegic patient to get to the stage where he can get out of bed to care for his own needs or from returning a coronary patient to competitive industry in a proper job as from making the diagnosis of monocytic leukemia or from controlling a case of ventricular tachycardia.[1]

Rehabilitation of the patient with heart disease involves the same basic principles and problems as rehabilitation of patients with any other type of disease. The term rehabilitation is defined as a process by which a patient is returned realistically to his greatest physical, mental, social, vocational, and economic usefulness and, if employable, is provided an opportunity for gainful employment in a competitive industrial world.[2] Rehabilitation has also been called restorative medicine.

The process of rehabilitation begins the moment the patient is first stricken with the disease, or at least when he is over the acute illness, and extends to the time when he is free of pain and out of the life-endangering stage. The need for rehabilitation is considered to exist in all etiological groups, in all economic groups, and in mild, moderate or severe cases. The greatest need for rehabilitation exists for the patient with a relatively mild or moderate case, who, in the opinion of Irvin,[3] has been most neglected. Rehabilitation of the cardiac patient in industry basically concerns patients with mild cases, since over 70% of cardiac patients in industry fall in classes 1 and 2 (New York Heart Association functional classification). Industry is apparently not aware of the ease and success in rehabilitating this large group of patients with mild cardiac conditions. While outstanding success has been attained in the rehabilitation of the few severely impaired patients, numerically the greatest need is in the patients with milder cases, among whom the success will be the greatest.

From the Department of Medicine, University Hospitals of Cleveland, and the School of Medicine, Western Reserve University.

Read before the Section on Physical Medicine at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

Important Factors

The specific goals of rehabilitation for the individual patient are variable for some merely to leave the hospital, for others to return to the world of society, and for others to return to competitive employment Regardless of the goal, each patient is eligible for rehabilitation to his maximal attainment

In approximately 80% of patients, the private physician can manage the total rehabilitation The other patients need the benefit of other disciplines (psychiatric, social service, occupational therapy, physiotherapy, and vocational counseling) and a team approach

Nature and Course of Heart Disease—The type of heart disease, extent of structural involvement, natural course of the disease, and extent of functional impairment are of major importance There is considerable variation in the course of a given patient's heart disease, *although, in general the prognosis is* quite predictable but subject to natural variations and to modifications by new methods of therapy As more is learned about the natural course of heart disease, the outlook becomes less unfavorable Dock[4] has recently compared the outlook of myocardial infarction with that of lobar pneumonia and considers it to be good and subject to improvement by dietary and other types of therapy The physician must know that spontaneous improvement does occur in a significant percentage of cases and that the course of heart disease is not necessarily downhill

Emotional Factors—In 46% of the patients studied at the Cleveland Work Classification Clinic, emotional factors were next in importance to the heart disease per se Much of this emotional difficulty was based upon fear anxiety and tension states that developed in previously susceptible individuals Even in the most stable patient the onset of heart disease is associated with periods of anxiety and depression The fear of death is often accentuated by publicity in newspapers and other mediums devoted to heart disease and by the economic and social pressures attendant on the development of heart disease

Emotional disability, however, often arises from the interrelationship of the patient and his doctor The patient's role in the genesis of iatrogenic disability is considerable There is often a purposeful or subconscious garbling or misinterpretation of the physician's remarks or attitudes to fulfill what the patient wishes to hear, a form of selective deafness or miscomprehension Heart disease often provides a strengthening of the patient's pre-illness basic needs, for example, an excuse to withdraw or flee from life's demands However, the physician's role may be more important The physician may be unwittingly careless in his words, attitudes, and management and thus contribute to the disability The physician may also be misinformed about the natural cause of heart disease or uninformed about the latest advances He may restrict the patient unnecessarily or misinterpret laboratory procedures

The physician's contribution to the emotional problems of heart disease may stem from secondary gains which the physician derives from the patient's continued disability These secondary gains can be considered to be psychological, financial, or professional Quite characteristically, anxious physicians have more anxious and desperate patients What are the gains, conscious or subconscious, for the physician in creating anxiety and disability? Crepe hanging, ominous prognosis of death, and overdramatization of the illness and its possible variations often reflect the psychological need of the physician to exert his power over life and death In other words, some physicians feel that, if they cannot prevent death, at least they can predict it with a flourish, often deriving great inward satisfaction from this

The physician may consider the terms impairment and disability to be synonymous Legally, total disability means the inability to resume a previous occupation The misinformed physician may disable his cardiac patient unnecessarily because he is unaware that most such patients suffer only slight impairment, let alone disability The physician should not embrace the popular idea that all patients with heart disease are to some extent incapacitated

In a few cases, iatrogenic disability has a financial connotation The more fearful the patient, the closer and more costly his medical care Sprague[5] has suggested that in a few cases the continued disability of the patient is financially beneficial to the physician

A different type of economic implication in medical overprotection rests on the fact that many physicians are fearful of returning the cardiac patient to work because a death claim might reflect on the physician's practice Often, however, the physician overprotects the patient in response to the patient's anxiety and to the pressures from the patient and his family or employer The gains may also be selfish in another way, that is, to further a favorite method of therapy Fear of impending death has been used to persuade asymptomatic patients with certain types of heart disease to submit to costly experimental procedures, the usefulness of which has not yet been clinically established beyond a doubt

Vocational Factors—Vocational factors include age race, previous training, literacy, educational background, work history and work performance, interest in hobbies, skill levels, and job opportunities The problem of transportation may be of prime importance The stresses of traveling to and from a job and the work involved in walking long distances to the place of employment may far exceed the energy expenditure required to perform the job Taxing features on the job, such as noise, dust, lifting, and incentive production, may be most important in determining the employability of a person with heart disease

Such other diseases of significance as diabetes mellitus, peptic ulcer, gallbladder disease, tuberculosis, arteriosclerosis, progeria, and neoplasm may complicate rehabilitation and prognosis

Management at Onset of and During Acute Illness

In the subsequent discussion it is assumed that adequate medical therapy is prescribed in all instances The importance of rest, relief of pain, restoration of oxygen system, adequate nutrition, and sedation is taken for granted Specific therapeutic and rehabilitative measures must be planned in detail to fit the specific needs of the patient

During Acute Episode—During the treatment of the acute episode, it is important, in order to prevent future disability due to fear, that the physician present to the patient a positive attitude, both hopeful and realistic, based on the knowledge that most patients recover from acute episodes of myocardial infarction pulmonary edema and congestive failure He must be able to restrict the patient's activity without constricting his ego, one of the most important tasks in rehabilitation

After Crisis—After the crisis is over, there is a need to explain the immediate and long-term prognosis to the patient and to his family The patient will need help in accepting the fact of his heart disease He should be informed in general terms of the plan of therapy and of the nature of his heart disease A concerted effort should be made to help the patient develop some insight into his disease and to encourage a receptive mood for future rehabilitation The rationale of such care as dietary control, cardiac medication, and use of diuretics should be presented to the patient in general physiological terms A simple description of heart function is well within the grasp of most patients During the process of explanation and education, a relatively optimistic attitude should be maintained The patient should not be advised that it will be necessary for him to change his whole way of living Nothing need be further from the truth, since 76% of the patients studied in the Cleveland Work Classification Clinic return to the same vocational and occupational classification

The physician should create an atmosphere to encourage the patient to talk, think, and act constructively about his illness and to participate actively in his own rehabilitation The period of passivity, which is frequently required in the treatment of myocardial infarction and rheumatic disease, should be terminated as soon as possible For the patient with coronary and hypertensive disease, enforced passivity is especially harmful, being the antithesis of his aggressive and dynamic personality

After the initial impact subsides, the attending physician should explain to the patient that he has had a heart attack, which consists essentially of a period of temporary deprivation of blood supply to an area of the heart The concept of collateral circulation and the process of muscle healing should be discussed The rationale of temporary restriction of physical activity should be explained, and the great capacity of the heart to recover should be stressed Articles dealing with the successful readjustment of other patients to their heart disease should be made available If the patient has rheumatic heart disease, the nature of the rheumatic process, the importance and feasibility of controlling streptococcic infection, and rheumatic recurrences should be dealt with If hypertension exists, the beneficial effects of rest periods, weight loss, sedation, tranquillity, and happiness should be considered

Hospital Convalescence—During the period of convalescence, which usually starts from the third to fifth day after hospital admission and ends approximately after three to four weeks in the hospital, the management of the patient differs from that of medical care which predominated during the first few days Here the team is organized, and the team approach should be put into action

Restrictions should be reasonable and individualized For the first several weeks the cardiac patient should be protected against communication with disturbing visitors, business associates, and relatives Business worries should be excluded or minimized whenever possible The patient should not be allowed free access to a telephone or allowed to conduct his business from the hospital bed Exception to these rules may be advisable, however A few minutes of discussion with an employer or a business associate may alleviate the patient's anxieties The use of tobacco and sexual intercourse should be forbidden during the first four to six weeks of the illness

Rest and Activity—The prescription for bed rest should be individualized, and bedfast invalidism should not be created More complete bed rest and quiet may be required for the first three to four days for the patient with myocardial infarction than for the patient with acute rheumatic disease or the hypertensive patient with congestive heart failure The patient should be in a comfortable position The period of passivity should be as brief as possible He should be encouraged not to lie motionless but to move actively from one side to another If seriously ill, he may require assistance He should be allowed to feed himself unless such exertion produces symptoms

Exertion in the form of graded exercise, such as flexing of the extremities, deep breathing, shaving, physiotherapy or occupational therapy, should be advised Details of the bedside chair treatment and early ambulation have been presented elsewhere by others Regardless of when the patient's activity is increased, the normalcy of the ill-effects of bed rest and the reaction of patients to exertion (tachycardia, slight dizziness, weakness, and anxiety) should be explained

During the convalescent period the full impact of the illness on the patient often becomes suddenly apparent Psychiatric effects of heart disease may suddenly appear in the form of anxiety, depression with anxiety, regression, paranoia, hypochondriasis, dependency, or denial of illness Throughout the illness the emotional status of the patient should be continually reevaluated The patient may conceive of himself as being more invalided than he really is These misconceptions should be sought out and corrected Usually superficial psychotherapy by the private physician suffices, but in approximately 10% of the cases psychiatric consultation may be required

The social worker may play an important role at this time for patients in all economic strata by helping the patient to use community facilities and to delineate the nature of the economic and family pressures If a patient's wife is young and if it is necessary for her to seek gainful employment, provision may be required for the children to be cared for and for other adjustments in the home to be made.

The rehabilitation of a patient with heart disease may be modified by associated diseases, such as diabetes mellitus and renal involvement, and particularly by thromboembolic complications. The details of management and rehabilitation of a patient with thromboembolism and especially hemiplegia have been summarized elsewhere. The outlook of the hemiplegic patient is by no means as hopeless as previously believed.[5] The majority of such patients can achieve self-sufficiency in the activities of daily living, and many can be selectively placed in jobs.

Convalescence at Home

The period of convalescence at home is variable in its duration and often is difficult to define. During this period, the ultimate goal is to increase the patient's activities gradually and safely. At the present time, the physician usually errs in the direction of excessive restriction and limitation.

Diet.—During the convalescence at home, dietary restrictions should be lightened, whenever possible, to a point that is bearable. The diet should be reasonable and practical and therapeutically indicated. Severe restriction of salt or truly low-fat, low-cholesterol diets should not be prescribed without proper therapeutic indications. Only patients with a demonstrated disturbance of cholesterol balance and fat metabolism should require such stringent diets. Unless there is a specific indication, mass prescription of restrictive, unpalatable diets is not advisable. The inability to follow such diets often produce considerable anxiety in the average cooperative patient. Actually, this anxiety may aggravate cardiac symptoms, thus interfering with the work adjustment period.

Removal of Restrictions.—An increase of activity allows more privileges and a methodical withdrawal of restraints. A positive attitude should be presented to the patient as to what is allowed rather than what is denied. A reasonable program would gradually allow the patient to eat more than one meal with his family and to extend his bathroom privileges and freedom about the home. The physician should encourage the patient to go up and down one flight of stairs once a day for a few days and then several times thereafter, at first slowly and later at a normal pace.

The beneficial effects of exercise upon the development of intercoronary collateral circulation has been experimentally demonstrated by Eckstein[6] and substantiated by clinical observation of the lower morbidity and lower mortality of physically active patients with coronary disease than those who are inactive.[7] After two or more weeks, short walks in the confines of the patient's home and yard, short diversional automobile rides, and later the driving of a car should be permitted. The patient should be allowed to increase his activities to the point of slight discomfort. The desire to return to the world of work should be nurtured by increasing the number of contacts with the outside world and helping the patient formulate work plans.

The restrictions on tobacco and physical activity, including sexual, should be lifted according to the individual case. The categorical denial of tobacco to all patients must be condemned vigorously, especially in patients to whom occasional moderate use of tobacco has significance. Most patients with heart disease can smoke moderately without apparent harm. Restriction of tobacco is probably warranted only if a patient is shown to have a sensitivity to nicotine and if significant peripheral vascular disease is present.

Evaluation of Fitness.—The fitness of the patient is reflected in his reaction to increased activity. It is important to recall the easy fatigability of a normal person who has been restricted to bed. There is a need for a dynamic approach in the evaluation of cardiovascular function. A profile of cardiac function is required in order to detect various types of failure of the circulation, i. e., blood pressure regulation, coronary circulation, myocardial failure, and failure of cardiac mechanism.

Measurement of Cardiac Reserve

During the convalescence at home and the work adjustment period the physician is faced with the need to evaluate the patient's cardiovascular functional status. A careful medical history is the principal clinical criterion of cardiac reserve, but its usefulness is limited by its subjectivity. Simple objective criteria are available today to judge a patient's recovery and his readiness for work. A patient's ability to perform ordinary home activities without dyspnea, angina, or other symptoms should be related to the energy cost of the whole range of physical exertion of humans. Measurements of the energy cost of many activities of humans have been made and are readily available. An excellent report was recently published by Passmore and Durnin[8] to which many references will be made. The physician today must be aware of ergometry and ergonomics, i. e., processes for dealing with the measurement of the energy requirements of activity of humans. This is especially important in the case of the cardiac patient whose energy capacity may be impaired by the basic heart disease.

The energy cost of such basal activity as sitting or lying is approximately 1.25 calories per minute. The calorie equivalent of oxygen is 4.8 to 5.0 calories per liter, i. e., one liter of oxygen consumed equals 4.8 to 5.0 calories of heat production. Skilled athletes using large muscle masses at maximal exertion (running, skiing) can increase their energy expenditure to a maximum of 26.5 calories per minute, while the maximal output for untrained men is about 14 calories per minute.[8]

Muller and Franz[9] estimate that the endurance limit of regular daily work for normal subjects averages 5 calories per minute, but the majority of modern industrial jobs require average energy expenditure of half that rate or less. A patient convalescing from acute heart failure or a myocardial infarct who is able to wash, shave, and dress (approximately 3 calories per minute) and walk around the block (6.6 calories per minute) is in all probability expending as much energy at home as he would at work. Recognition on the part of the physician of the relatively high energy cost of such simple ordinary activities will enable him to advise the patient to resume work without a fear of overtaxing the patient's heart.

An even more objective estimate of cardiac reserve may be obtained from the familiar Master two-step test. Recent studies in our laboratory have confirmed the sound physiological basis of this test, which imposes the same caloric work load on subjects of various ages and weights.[10] These studies also emphasize that by observing the recovery rate of pulse and blood pressure as well as the usual electrocardiographic changes the physician can obtain a more detailed profile of the patient's response to exercise. Pulse and blood pressure should both return to within 10 points of resting level by two minutes after exercise. If the patient can perform the exercise without symptoms, an abnormal pulse rate or blood pressure, or electrocardiographic changes, it is safe to recommend that he undertake most types of industrial employment. If abnormal responses are noted, he still may be able to perform an average job, since the step test requires an energy output of 8.5 calories per minute, which is much greater than the average demand of representative jobs and considerably greater than the peak demands of these jobs (see table).[11]

Energy Expenditures, in Calories per Minute, During Typical Working Day for Thirty-six Persons with Heart Disease

Category	Av	Peak
Less than 1		
Electronics tester	0.70	0.98
1-1.5		
Laundry crib supervisor	1.25	1.47
Maintenance electrician	1.26	2.87
Gauge setter	1.28	1.80
Tool crib attendant	1.40	2.68
Painter	1.41	2.07
Foreman	1.46	2.35
1.5-2		
Planning clerk	1.68	2.01
Supervisor	1.71	2.22
Boxmaker	1.74	2.17
Drill press operator	1.77	2.02
Foreman	1.78	4.04
Plant guard	1.82	4.12
Tool grinder	1.84	2.23
Shift foreman	1.85	2.58
Light assembler	1.88	2.40
Inspector	1.92	3.77
Assembler	1.96	2.49
Light assembler	1.98	2.92
Stock picker	1.99	3.34
2-2.5		
Stock picker	2.00	2.62
Set up burnishing press worker	2.04	2.25
Stub lathe operator	2.07	2.74
Millwright (maintenance)	2.15	2.63
Stamper	2.16	4.31
Maintenance supervisor	2.18	3.77
Scarfing machine operator	2.26	3.26
Drill press operator	2.27	2.93
Turret lathe operator	2.28	2.78
Matron	2.36	4.11
Clutch tester	2.40	2.52
2.5-3		
Welder	2.60	4.47
Supervisor	2.67	3.22
Janitor	2.69	4.29
Fireman (boiler)	2.75	0.72
Over 3		
Stock picker	3.05	4.39

An integrated picture of the patient's recovery and improving cardiac reserve can thus be obtained by any physician during the period of convalescence. A careful history and therapeutic and functional classification employing the New York Heart Association criteria become more meaningful in the light of energy expenditure data, since there is an agreement in over 75% of the cases between this therapeutic and functional classification and the fitness as determined by physiological testing.[12]

Jones[13] writes that Class 1 cardiac patients can do 4.0 to 6.6 calories of work per minute, class 2, 2.7 to 4.0 calories per minute, and class 3, 2.7 calories per minute or less. The usual laboratory criteria used to note the recovery from an acute cardiac illness, such as temperature, erythrocytic sedimentation rate, transaminase levels, and electrocardiogram, provide further guideposts. Finally, the response of the blood pressure, pulse rate, and electrocardiogram to the measured stress of the Master two step test provides a scientific estimate of cardiac reserve.

Work Adjustment Phase

The decision that the patient may return to work initiates a new and critical phase of rehabilitation. In the absence of work classification units or rehabilitation services, the principles of a multidisciplinary approach can nevertheless be employed successfully by the private physician in most communities. Ideally a team should be used, consisting essentially of the private physician, industrial physician, employer (personnel manager or foreman), vocational counselor, and social worker. These individuals are united in an effort to match the patient's total capacity with the demands of the specific job.

Industrial job evaluation considers four aspects: (1) skill, (2) effort, (3) working conditions, and (4) responsibility. To the cardiac patient, effort and working conditions are of primary significance, although emotional factors, which include reaction to responsibility, are also important.

The effort required by a great many of the possible occupations in America nowadays is surprisingly small and not significantly greater than that required by ordinary home activities. Little wonder that many cardiac patients prefer to work than to remain at home. Reference has been made to the growing body of information available regarding the energy costs of various activities.[8] Our experience with 1,100 patients of the Work Classification Clinic of the Cleveland Area Heart Society and our current on-the-job studies[11] confirm the fact that actually cardiac patients, observed under actual working conditions and followed clinically over six years, are working at a wide variety of jobs without evidence of undue physiological stress.

A specific job description should be obtained by the vocational counselor and confirmed by the personnel manager or other representatives of the employer. The concept of the standard job is of no use, because there are so many variations in the requirements of the same job in a plant or in different plants in the same industry. The pattern of energy expenditure is apt to be more important than the magnitude. The frequency of rest periods, pauses, and relief of boredom are important factors. Our comparative studies of normal subjects and cardiac patients show that the same job performed by men of the same age and same skill require approximately the same energy Energy expenditures vary more on the basis of personality needs of the worker than on the basis of energy requirements of the job

Often a simple adjustment or job modification can be made in order to eliminate a single peak energy load which would make the job otherwise impossible For example, a fellow-worker might tighten a lathe chuck or lift heavy parts in place for the worker with cardiac disease A brief conference with the employer or union steward may make it possible for a relatively simple change in working conditions to be made which would make a job more suitable

Observations of cardiac patients at work[11] demonstrate that in many jobs walking constitutes much the heaviest and most sustained exertion and that a rough estimate of the total energy requirements of a job may be obtained from the amount of walking involved The estimation of the total energy requirements must include the energy expended in extracurricular activities, in travel to and from work, and the total work energy requirements of the job itself

Fatigue

Fatigue is a problem which is just being defined at present, and no good measurement of it is available Studies to date, however, indicate that the psychological factors are predominant over simple energy expenditure, particularly at the level of exertion which might be considered for a worker with a cardiac condition

Working conditions, in the sense of physical environment, may be of great importance in individual cases A given energy expenditure will be much more stressful to the cardiovascular system under conditions of excessive heat than under normal conditions Fortunately, however, heat and humidity control are being applied throughout all industry, including the proverbially inclement steel industry Modern industrial physicians no longer think primarily in terms of "cardiac jobs" It is becoming increasingly evident that all but jobs requiring severe physical exertion (over 6 calories per minute) may be, or may be easily made, suitable for the majority of cardiac patients

The emotional milieu of the job may be more important than its energy requirements to the patient with angina or other conditions with recognized emotional facets Here the social worker may play a key role in recognizing the importance of the status of the job and the stress imposed by an overdemanding employer, by the pressure of competition in a piecework job, or by the patient's having accepted responsibility for which he feels unfit Although the influence of the economic and family pressures generated at home may prevail during the working hours, more commonly the opposite pertains, viz, many patients have their attacks of angina only at home and not at work It should be emphasized, however, that in almost all cases the satisfaction, restoration of self-respect, and relief of financial worry, which are the result of the return to work, outweigh any detrimental emotional stress associated with a job A suitable job thus must provide status, self-esteem, and remuneration and be within the patient's present and future capacity

After the emotional and physical factors are considered, the patient often cannot be returned to his previous occupation This occurred in 24% of the cardiac patients studied in the Cleveland Work Classification Clinic If job modification cannot be effected on a local level or selective placement obtained, the private physician may be forced to enlist the help of other disciplines, particularly vocational counseling and testing services and rehabilitation and placement services

Comment

The physician today finds himself burdened with cares which seem far removed from the "pure" domain of scientific medicine Indeed it is fortunate that the cardiovascular capacity of the cardiac patient is so great and the energy requirements of industry so low that the physician does not have a greater percentage of patients who require the multidisciplinary approach In approximately 42 cities in the United States today there are special work classification clinics, which relieve the private physician of these responsibilities in difficult cases These clinics, supported by the American Heart Association, have proved their value in demonstrating that a person with heart disease can work safely in a variety of jobs

We have already referred to our experience in the Cleveland Work Classification Clinic with 1,100 patients in the past six years The team approach, with the team consisting of the medical social worker, vocational counselor, and cardiologist, has been employed successfully Workers with representative heart disease have been studied, and results of the studies have fortified many of the concepts presented earlier From the complexity of the needs of patients with heart disease, which include vocational guidance, vocational rehabilitation, physical rehabilitation, interpretation, and reassurance, it would seem that the nonintegrated approach would be unsuccessful in most of the above-mentioned cases and that the final management of the majority of such cases by one physician alone would have been inadequate As mentioned before, the emotional problems are important In 46% of the cases, the emotional impact of the illness on the patient was more important than the organic heart *disease itself*

Follow-up studies have confirmed the practical value of selective placement of cardiac patients in industry There have been no medicolegal compensation cases involved in the employment of such patients There has been no evidence that employment has aggravated the underlying heart disease In the experience of several work classification clinics, 70 to 75% of the cardiac patients have improved or remained unchanged while working Follow-up studies have revealed that of the original group who were unemployed at the time of the first visit 60% were subsequently employed The clinic team approach has enabled persons with heart disease to return to the status of wage earners, to gain selective placement, to obtain new jobs, to work safely in a variety of occupations and industries, and to adjust more satisfactorily to their heart disease

Summary

The factors important in the rehabilitation of the patient with heart disease include (1) nature and course of heart disease, (2) emotional reaction, (3) iatrogenic disability, (4) vocational features, and (5) presence of other diseases In the management of such a patient, the need to prevent iatrogenic disability and cardiac neurosis and to expedite physical and emotional rehabilitation is important Measurement of the patient's functional capacity in physiological and ergonomic terms is valuable in the regulation of the rate of rehabilitation and in matching the patient's capacity with the demands of specific jobs

PROBLEMS OF RETAINED AND RECURRENT COMMON BILE DUCT STONES

Seth W Smith, M D, Charles Engel, M D, Beryl Averbook, M D
and
William P Longmire Jr, M D, Los Angeles

• *A series of 1,381 initial biliary tract operations for calculous disease has been analyzed with respect to stones that escape detection during operation or form de novo after operation The two kinds are often indistinguishable, and both are referred to as "retained stone" After 224 cholecystectomies with choledocholithotomy there were 14 cases of retained stone, after 1,156 cholecystectomies without choledochotomy there were only 9 cases of retained stone Once the diagnosis of retained stone is established with reasonable certainty, reexploration is generally indicated In this series, 22 patients underwent a second operation and four underwent a third The unfortunate occurrence of retained stone is thus more frequently encountered after previous choledocholithotomy and the presence of a biliary duct stone indicates a possible source of serious difficulty*

Although the problem of retained and recurrent stones in the common bile duct has received considerable attention over the years and although many excellent studies have been reported by Johnston, Waugh, and Good,[1] Glenn,[2] Buxton and Burk,[3] Cole,[4] Paine and Firme,[5] McKittrick and Wilson,[6] and others, the management of these difficult cases still poses a serious problem to the individual surgeon when he is faced with evidence of continued abnormality within the common duct after surgery on the biliary tract

The decision as to whether a stone detected in the biliary ducts after surgery is retained or recurrent is in some cases an arbitrary one Of the 24 patients in this study, in 15 the stones were definitely retained, and in 4 they were felt to be recurrent on the basis of long symptomatic intervals involved, the type of stones in the remaining 5 could not be determined with any degree of certainty Consequently, in the interest of simplification, no effort is made in the following report, except in certain instances, to continue the distinction between retained and recurrent stones, and thus they will be loosely referred to as "retained"

The reported incidences of gallbladder and biliary duct stones in the population at large are somewhat variable On the basis of 16,936 autopsies of individuals of all ages, performed at the Mayo Clinic between 1910 and 1942, Robertson and Dochat[7] reported a 16 3% incidence of gallstones, 12 6% of 10,587 men and 22 6% of 6,349 women had gallstones Glenn[2a] states that a safe estimate of the incidence of gallstones would be at least 10% for the general population of the United States and 20% for the population over the age of 40 years Stones in the gallbladder,

---

From the Department of Surgery, University of California Medical Center and Wadsworth General Hospital, Veterans Administration Center, Los Angeles, and Los Angeles County Harbor General Hospital Torrance, Calif

Read in the Panel Discussion on Common Duct Stones before the Section on Surgery, General and Abdominal, at the 105th Annual Meeting of the American Medical Association, Chicago June 14 1956 increase in incidence with the passage of years, showing a considerable rise in the 35-to-55-year group Robertson and Dochat [illegible] found that 22 3% of women and 9 7% of men in the fourth decade had gallstones In persons over the age of 55, the increase progresses less sharply, but it is estimated that one out of three individuals will have gallstones at the age of 75 The incidence of common duct stones also increases with advancing age, and autopsy records indicate that one-third to one-half of individuals over the age of 80 years with cholelithiasis will be found to have biliary duct stones Such stones are infrequent, however, in individuals under 40 years of age

After common duct exploration, with or without removal of stones, the incidence of retained stone has been reported by various authors to vary from 3 to 10%[8] Few reports have appeared concerning the incidence of retained or overlooked stones after negative common duct explorations Buxton and Burk[3] noted retained stones by postoperative cholangiograms in 9 (4%) of 249 persons who underwent negative choledochotomies, in 3 of these patients (1 2%), the stones were later removed surgically Glenn[2b] performed follow-up studies of 3 to 18 years on a group of 100 patients who had cholecystectomy and choledochotomy No stones had been found on primary exploration in 46 of these patients, but calculi were recovered from the biliary ducts in 2 of these 46 (4 2%) on reexploration

TABLE 1 —*Incidence of Retained Stones After 1,381 Biliary Operations*

First Operation	Total Patients No	Patients with Retained Stones No	Patients with Retained Stones %
Cholecystectomy	1 156	9*	0 8
Cholecystectomy with choledochotomy	224	14†	
Choledochotomy only	1	1	6 7
Total	1 381	24	1 7

* Found in one patient at autopsy

† Second operation not yet performed on one patient Diagnosis by cholangiogram

The incidence of retained stones after choledocholithotomy has been reported by various authors to vary from 5 8 to 28% (table 8, below) As will be discussed more fully below, it would appear that the incidence of retained stones after choledocholithotomy performed by experienced surgeons would approximate 8 to 9%

Finally, it is of interest that the incidence of retained stones or of stones discovered in the biliary ducts after cholecystectomy without biliary duct exploration is surprisingly low Glenn[2b] followed up 100 consecutive patients who had had cholecystectomy more than 10 years prior to his study Seven of these had symptoms leading to common duct exploration, and stones were found in four Thus, an accurate incidence of 4% of retained stones after cholecystectomy is given

Case Material

Initial Operations—A total of 1,381 initial biliary tract operations for calculous disease has been reviewed (table 1) These cases are collected from the records of three hospitals the Wadsworth General Hospital, Veterans Administration Center, Los Angeles, the Los Angeles County Harbor General Hospital, Torrance, and the University of California Hospital, Los Angeles, for the period from Jan 1, 1947, to March 1, 1956, inclusive

TABLE 2 —*Incidence of Retained Stones After Choledochotomy With and Without Removal of Stone*

	Total Patients No	Total Patients %	Patients with Retained Stone No	Patients with Retained Stone %
Stone removed	123	55	14	11 0
No stone found	102	45	1*	0 95
Total	225		15	

* It is not known whether the stone is retained or recurrent in this case

The various incidences of retained stones in this study are inaccurate because of certain inadequacies of follow-up Some patients have not been followed up for a long time, especially those who have undergone second and third operations, and others have been lost to follow-up Furthermore, an undetermined number with retained stone undoubtedly went elsewhere for their second operation The group of six patients with retained stones in the University Hospital, however, were of this itinerant nature, having had their first operation performed at hospitals other than one of the three included in this study Thus, to an undetermined extent, this elusive factor would tend to be balanced

Except in the University Hospital, the bulk of the operations were performed by surgical residents Twenty-four instances of retained (and recurrent) stones occurring subsequent to the first biliary operation were found, representing 1 7% of the total Nine of the 24 followed 1,156 cholecystectomies (0 8%) and 15 followed 225 common duct explorations, associated with cholecystectomy in all but one case, an incidence of 6 7% (table 1) Of the total of 225 patients who underwent choledochotomy, 123 (55%) had stones removed and in 102 (45%) no stones were found (table 2) There were 15 instances of retained stones after cholodochotomy 14 after previous choledocholithotomy (11%) and one after negative common duct exploration (0 98%)

TABLE 3 —*Incidence of Retained Stones After Second Operation*

Second Operation Type	No Patients	Patients with Retained Stones After Second Operation No	Patients with Retained Stones After Second Operation %
Choledochotomy	20*	5†	25
Choledochotomy with choledochoduodenostomy	1	0	0
Choledochotomy with choledochoplasty	1	1‡	(100)
Total	22	6	27.2

* In 9 of these patients initial operation was cholecystectomy

† Retained stones found at autopsy in 2 patients

‡ Stricture present possibly due to stone

Of the 24 patients with retained stones, 12 were female and 12 male With the group of 10 males at the Veterans Administration Hospital excluded, there were 12 females and 2 males The age of the 24 patients varied from 26 to 76 years, with a median age of 62

Second Operations—As shown in table 3, a second operation, consisting of common duct exploration, was performed on 22 of the 24 patients with retained stones Retained stones were diagnosed by autopsy in one of the other two patients and by a postoperative cholangiogram in the other, who has not yet undergone a repeat operation Common duct exploration was repeated in 13 of the 22 patients undergoing repeat operation In the remaining nine patients, however, the initial operation was cholecystectomy, hence, common duct exploration, the second procedure, was performed for the first time In addition to common duct exploration, one patient had a cholecystoduodenostomy and another a choledochoplasty

Third Operation—Twice-retained stones occurred in six patients, or 27 2% of those requiring a second operation In two of the six patients the stones were found at autopsy, while four patients underwent a third operation (table 4) Of these four patients, all are progressing well except one (case 1), who had multiple intrahepatic stones and in whom an operative cholangiogram indicated possible further retained stones In another the gallbladder was removed at the third common duct exploration

A total of 26 second and third operations were thus necessary in the 24 patients with retained or recurrent stones, and one patient may require a fourth operation The operation performed was common duct exploration in all instances This was combined with choledochoduodenostomy in one case with choledochoplasty in two, and with cholecystectomy in one Because of the recurrent status of some of the stones for which second and third operations were necessary, the incidences of true retained stones are altered This factor is analyzed in greater detail in the Comment below

Cholangiography

Operative Cholangiography—Operative cholangiography was used in only three instances in connection with the 24 patients of this series Its use in the total of 225 common duct explorations has not been determined Although not yet a routine procedure, it has been performed with increasing frequency within the last two to three years covered by this study, but not sufficiently to be evaluated in this report

TABLE 4—*Patients upon Whom Three Operative Procedures Were Performed Because of Retained Stones*

Case No	Operation 1st	 2nd	 3rd
1	Cholecystectomy	Choledochotomy	Choledochotomy
2	Cholecystectomy	Choledochotomy	Choledochotomy
3	Cholecystectomy	Choledochoplasty (stricture possibly due to stone)	Choledochoplasty (stricture due to stone)
4	Choledochotomy	Choledochotomy	Choledochotomy and cholecystectomy

* This patient may require still another choledochotomy

Postoperative Cholangiography—Cholangiography was performed postoperatively, with use of the inlying T tube, in 29 instances (table 5) It was performed after initial common duct exploration in 12 patients, definite evidence of obstruction by retained stones was seen in 9 of them and dilated ducts in 2, and only one was reported as normal The presence of retained stones was verified by common duct exploration in 11 and by autopsy in one After a second common duct exploration, cholangiography was done in 15 patients, obstruction by stone was revealed in 2 and dilated biliary ducts in 3, and a normal reading was obtained in 10 The presence of retained stones was verified by subsequent common duct exploration in the two patients showing obstruction, and, at autopsy, two years later, stones were revealed in one of the patients with dilatation of the ducts No further operations have been performed on the remaining two patients with dilated ducts or the 10 with normal cholangiographic findings Two cholangiograms made after a third common duct exploration were read as normal These data help to confirm the established value of the postoperative cholangiogram in the management of biliary stones

TABLE 5—*Relation of Findings on Postoperative Cholangiography and Subsequent Choledochotomy*

Previous Operation	Patients No	Findings Obstruction	 Dilated Ducts	 Normal	Stone Verified by Choledochotomy
First	12	9	2	1	12*
Second	15	2	3	10	3*
Third	2	0	0	2	0
Total	29	11		13	15

* Stone verified in one case by autopsy

Intravenous Cholangiography—Intravenous cholangiography was utilized eight times Findings were normal in two patients Stones were visualized in three patients and later identified by operation in two (one patient has not yet had a second operation) Retained stones were likewise later positively identified in one patient in whom there was nonvisualization of the ducts and in two patients with dilated biliary ducts but in whom no stones were seen on cholangiography These data are meager and only support the observations by others that intravenous cholangiography, because of the effects of altered hepatic function and difficulty in visualizing the distal common duct, cannot positively indicate the absence of stones [9]

Biliary Fistula

In this series, persistent biliary fistula occurred three times In one patient, a calculus was demonstrated at the ampulla of Vater by cholangiogram two weeks postoperatively the T-tube was removed after three weeks, and a biliary fistula persisted until the stone was removed by a second common duct exploration two months later In the second patient, fistula occurred two months after choledocholithotomy and two incisions and drainages of subhepatic abscesses A small stone at the ampulla of Vater and many in the hepatic ducts were removed one month later, or three months after the initial operation The third patient developed a biliary fistula after cholecystectomy Stones were passed through this fistula for two and one-half years, and then it healed After four years several stones were removed from the cystic duct stump and from the common duct This case supports the observation by Hicken and co-workers[10] that some biliary fistulas eventually heal even in the presence of retained calculi

Biliary Flush

Best's technique of biliary flush[11] was tried in four instances in an effort to remove stones definitely identified by cholangiogram In no instance was it successful, all stones being removed eventually by choledocholithotomy

TABLE 6 —*Incidence in Other Series of Retained Stones After Choledocholithotomy*

Comment

The data obtained from this study and from those of others shed light on two questions regarding the problem of the retained stone that concern the surgeon performing operations on the biliary tracts 1 Are most retained stones overlooked because the common duct is not explored or are most of these overlooked during exploration? 2 Are the majority of retained stones overlooked during common duct exploration where stones were identified and removed, or are they overlooked and retained during explorations where no stones were found? In answer to the first question, as shown in table 1, the incidence in our study of retained stone was 0 8% after cholecystectomy alone but 6 7% after common duct exploration with or without identification and removal of stones Although these percentages are probably lower than the absolute incidences because of inadequacies in follow-up, the ratio of one to the other is probably fairly accurate In answer to the second question, in our series retained stones were found after choledocholithotomy in 11% and after common duct explorations where stones were not found in only 1%

These data indicate that, if the surgeon explores biliary ducts, adhering to the accepted indications (palpable stone, dilated duct, thickened wall of the duct, gallbladder with small stones and large cystic duct, and a history of jaundice with pain), his chances of leaving stones in the unexplored duct after cholecystectomy alone are gratifyingly low The incidence in our series of stones found in explored ducts is 55%, and in other published reports the incidence varies from 33% to 69%, with a rough average of around 50%

These and other published data show that most stones are retained after choledocholithotomy, a clinically significant fact in that an individual harboring stones in his biliary ducts possesses a source of potentially serious difficulty Operative experience and awareness of the problem presented by biliary duct stones would appear to affect significantly the incidence of retained stone after choledocholithotomy performed by any individual or group of surgeons, to some extent this is reflected in the published literature (table 6)

Neither our data nor those published in the literature, which is scant in this regard, allow the formulation of any sort of rule-of-thumb estimate as to how many patients undergoing a second operation for retained stones will require a third exploration for twice-retained stones Our series (table 3) reveals that 6 of 22 patients, or 27 2%, still had retained stones after second operative procedures Three of the 22 patients were operated on for recurrent stones and 5 for possible recurrent stones, hence, the corrected percentage of second operations for true retained stones would be 14% Six patients still harbor stones in the common ducts after two previous operative procedures, in three of these patients stones were retained after attempted removal of probably recurrent stones and in three the stones were truly twice-retained As the retained stones in two of the six patients were found at autopsy after death from unrelated causes, a third operation was necessary in only four (table 4) In this group of four, one patient, who originally had cholecystectomy alone, followed by two common duct explorations for large numbers of extrahepatic and intrahepatic stones in each instance, still has indications of thrice-retained stones, and a fourth operative procedure may be necessary in the future These cases illustrate that it may be very difficult to rid a small percentage of patients of all biliary stones and emphasize the importance of the problem presented by intrahepatic stones Norman[12] found that, of 46 patients with verified hepatic calculi, 31 also had stones in the intrahepatic ducts It was impossible in 18 patients (in 14 of whom the stones were definitely intrahepatic) to remove all the hepatic stones visualized in cholangiograms made at operations As a result, choledochotomy was repeated in 7 patients, and, finally, in 26 of the 46 patients, calculi were left in spite of choledochotomy In his thorough study, Norman points out the value of operative cholangiography performed both before and after the duct is opened and stresses the importance of radiographic technique utilizing exposure of the plates at various angles in order to avoid superimposition of intrahepatic ducts on one another

TABLE 7 —*Type of Stones Detected After Biliary Surgery*

Initial Operation	Patients No	No of Patients with Retained Stones	Recurrent Stones	Stones of Undetermined Status
Cholecystectomy	9	4	3	2
Cholecystectomy and choledochotomy	15	11	1	3
	24	15	4	5

The surgeon is also concerned with knowing how soon a retained stone will make itself evident if overlooked at the time of common duct exploration Retained stones in 15 of the 24 patients in this series showed definite evidence of their retention early in the postoperative period Three of the 15 patients had persistent biliary fistulas, in 10, obstruction of the duct by calculi was demonstrated by postoperative cholangiogram, and in 6 significant symptoms were present postoperatively

It is of interest that more stones that were believed to be recurrent were found after cholecystectomy alone than after cholecystectomy with common duct exploration (table 7)

This study confirms the value of the postoperative cholangiogram, which was performed in 29 instances (table 5) Obstruction was found in 11 instances and dilated ducts in 5, the presence of stones was subsequently verified by operation or autopsy in 15 of these 16 cases The diagnostic accuracy of the postoperative cholangiogram, as indicated in this and in numerous other studies, is sufficient to indicate the advisability of using the T-tube after each common duct exploration for stone Furthermore, the T-tube should not be removed until cholangiography has been done and the most accurate knowledge possible has been gained concerning the patency of the common duct

- The surgeon is also interested in knowing whether a retained stone should be immediately removed surgically or whether and to what extent watchful waiting or nonoperative methods, such as biliary flush, will result in passage of the calculus Johnston, Waugh, and Good[1] saw 12 patients with residual common duct stones, diagnosed by postoperative cholangiograms in 11 and by symptoms in one, and found a second operation to be necessary in only 6 Evidence of stone subsided in five, and the remaining patient died and did not come to autopsy The data in our series are inadequate to indicate definite answers to these questions Twenty-two of our 24 patients with retained stones eventually had stones removed at a second operation, retained stone was diagnosed at autopsy in one of the remaining 2, and in the other a second operation has not yet been carried out In 9 of the 22 patients the interval before the second operation was from 18 months to 33 years, and during these periods these patients experienced asymptomatic intervals, some of many months' duration Difficulties related to the biliary tract continued to reappear, however, until all stones were removed These results suggest that, once the diagnosis of retained or recurrent common duct stone is established with reasonable certainty, common duct exploration without delay is generally indicated

Although our use of Best s method of biliary flush[11] was unsuccessful in the four instances in which it was tried, other authors[13] had had varying degrees of success with his method and with that of Pribram[13c] Glenn[2a] states that he has abandoned the use of the latter method because of reactions and delayed cholangitis that followed the use of the solvents advocated Singleton and Coleman[13f] recently reported that 'most authorities have found no harmful effects" from the use of chloroform and ether and point out the importance of agitating the stone by irrigation to effect its dissolution It would appear that success with these methods depends in large part upon the degree of patience exerted by the user and also on the fortitude of the patient and his desire to avoid another operation

Summary

Twenty-four of 1,381 patients had retained or recurrent common duct stones after operations for calculous biliary disease The incidence of retained and recurrent stone after cholecystectomy appears to be 4% or less This percentage is apparently due to the liberal exploration of the common duct by most surgeons, who have adhered to the indications currently recommended The incidence of retained and recurrent stone after all common duct explorations appears to be in the range of 3 to 10%, after negative explorations, it is approximately 4%, but after previous choledocholithotomy by experienced surgeons, the incidence appears to be about 8 to 9% The unfortunate occurrence of retained stone is thus more frequently encountered after previous choledocholithotomy, indicating that the presence of biliary duct stones per se may be the major source of serious difficulty for the patient (and the surgeon)

In our series of 24 patients with retained and recurrent stones, 22 underwent a second operation, 4 underwent a third operative procedure, and one may require a fourth operation, illustrating the difficulty of finally ridding a small percentage of patients of biliary duct stones Due to the fact that operative cholangiography has been employed by us only in the latter part of the period studied, its value cannot be accurately evaluated Use of the postoperative cholangiogram was sufficient to confirm the value of this procedure The T-tube should be used after each choledochotomy and should not be removed until at least one postoperative cholangiogram has been obtained Our study indicates that difficulties related to the biliary tract continued to reappear until all stones were removed surgically Therefore, once the diagnosis of retained or recurrent common duct stones is established with reasonable certainty, reexploration is generally indicated

PRACTICAL VALUE OF OPERATIVE CHOLANGIOGRAPHY

C Allen Wall, M D
and
S Patrick Peartree, M D, St Louis

- *Cholangiography can be performed during operations on the biliary system by injecting the contrast medium through the cystic duct before exploring the common duct or by injecting through the T tube after exploration The film is exposed during a brief period of apnea induced by the anesthesiologist, and while the film is developed the gallbladder can be removed Cholangiograms with sodium acetrizoate as the contrast medium were made in 444 patients The common duct was explored in 231, and calculi were recovered from the ducts in 115 Stones missed on operative exploration were detected by operative cholangiography in 36 patients Postoperative complications have occurred, and both false-positive and false negative results have been noted These difficulties can be reduced by attention to details, and the usefulness of the results has been demonstrated*

It is self-evident that the best way to manage stones within the extrahepatic biliary ducts is to recognize their presence and remove them[1] It is our purpose to discuss the role of operative cholangiography in furthering this objective

The subject of operative cholangiography is a controversial one The controversy revolves around the accuracy of the technique in relation to the alleged disadvantages of its use[2] Certain questions arise Does this additional diagnostic adjunct enhance the thoroughness of an operative exploration of the ducts? Will a more general adoption of this procedure reduce the number of unnecessary common duct explorations? Is the additional inconvenience justified by the results obtained? These are pertinent questions attending the use of this procedure to which our data will be applied

Our observations are drawn from an experience with operative cholangiography in 444 patients In this presentation only certain practical observations derived from the data are presented A more detailed analysis is presented elsewhere[3]

Case Material

Four hundred forty-four patients were subjected to operative cholangiography during the past four years These patients were drawn from the surgical services of the St Louis University Hospitals, more than four-fifths of the procedures were performed by the resident staff In 57%, cholangiography was performed through the cystic duct prior to exploration In 32%, the common duct was explored and contrast medium injected through the T-tube after exploration In 11%, both preexploratory and postexploratory operative cholangiograms were done The common duct was explored in 52% of the 444 patients Calculi were recovered from the ducts in half of the explorations (26%)

Technique

The standardized technique used in this series is diagrammatically illustrated in the figure Certain points may be emphasized Wound drapes should be sutured to the skin, and all radiopaque sponges and instruments must be removed from the right upper quadrant before injection of the agent The absence of bubbles in the system is insured by aspiration of bile into the syringe We have used with satisfaction a 70% aqueous solution of sodium acetrizoate, injected in increments of 5, 5, and 10 ml, with exposure of a film after each injection It is important to inject slowly to avoid raising the intraductal pressure

The need for cooperation between the surgeon, anesthesiologist, and radiologist has often been stressed After injection of the contrast medium, the anesthesiologist induces a state of apnea and instructs the technician to expose the film During the short period while the films are being developed, the gall bladder may be removed With proper teamwork there is minimal prolongation of the operating time

Indications for Operative Cholangiography

Operative cholangiography may be helpful in two sets of circumstances. First, after either a positive or a negative operative exploration of the common duct, it may serve as additional insurance against retained stones. Second, when the indications for exploration are questionable, the operative cholangiogram may help to solve the surgeon's dilemma. If stones are demonstrated by cholangiography, exploration is mandatory. If the cholangiogram is negative, the surgeon may refrain from opening the duct with greater assurance that stones are not being overlooked.

In this series the reasons for the use of operative cholangiography were as follows. In a small number of patients (17%), the procedure was used to help evaluate the method. In more than four-fifths of the patients, it was felt that operative cholangiography would be a useful adjunct in reducing the incidence of overlooked common duct stones. Thus, operative cholangiography was performed to insure against retained stones in 42% of the patients (after positive exploration in 22% and negative exploration in 20%) and to avoid unnecessary exploration of the duct in 41%.

In certain instances one is compelled to explore the common duct. When there is palpable stone, a dilated or thickened common duct, bile containing particulate matter, or an acalculous gallbladder in the presence of typical biliary colic, as well as in certain types of jaundice, the indications for exploration are clear-cut. However, in selected patients with a history of jaundice or pancreatitis and with no operative evidence of common duct obstruction, the indications for exploration are less clear. Moreover, exploration of the common duct in every patient with multiple small stones in the gallbladder would result in a number of needless explorations. In such instances the surgeon may be undecided whether to open the duct. Under these circumstances, what help may be expected from operative cholangiography? A review of our own experience sheds light on this question.

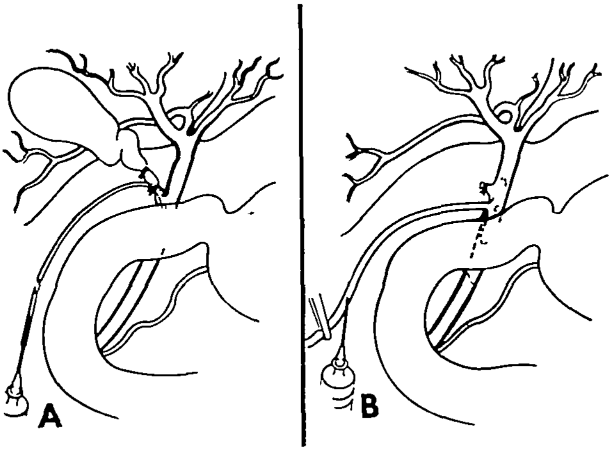
The over-all diagnostic accuracy of the method in these 444 patients was 88%. This relatively high figure is an index of the attention directed to technical precision, which is so important in obtaining satisfactory cholangiograms. In 63 patients (14%) stones were seen on the operative cholangiogram. In 36 of these 63 patients, the common duct had been explored and judged to be free of stones. In these 36 patients, the retained stones lay within the common duct in 24 instances and within the hepatic ducts in 12. In all but two patients (both with hepatic duct calculi), the stones demonstrated on operative cholangiography were removed on immediate reexploration of the duct. In the two patients with stones in the hepatic ducts, repeated efforts at extraction were unsuccessful. Delayed cholangiograms during the postoperative period revealed that the stones in both instances had dropped from the hepatic radicle into the common duct, both were removed at a second operation.

In evaluating the usefulness of this procedure, one must consider whether the additional time, expense, and inconvenience of operative cholangiography in 444 patients was justified in order to remove stones that would otherwise have been retained in 34 patients. Certainly some of these patients would have required a second operation for removal. In those who were spared a second procedure because of operative cholangiography, there is no doubt as to its merit.

In 144 patients with questionable indications for exploration but with no direct evidence at operation of a stone within the duct, the decision against common duct exploration was abetted by a negative operative cholangiogram. Such a decision is always open to question until complete, long-term follow-up establishes its correctness.

Problems Encountered

The method was judged to be unsatisfactory in 12% of the patients in this series. More than half (6.5%) of these poor results were due to errors in technical performance. These errors included poor positioning of the patient, motion during exposure of the film, interposition of opaque objects, extravasation of the contrast medium, and faulty radiographic technique.



Technique used for operative cholangiography, *A*, before exploration and, *B*, after exploration.

The remaining unsatisfactory results were due to errors in interpretation of the films, with 3.5% false-positive and 2% false-negative.

It is useful to review some of the more common reasons why a surgeon may be misled by the cholangiogram into searching for a 'stone' that does not exist. These false positive results are occasioned by incomplete filling of the hepatic ducts, spasm of the ampulla preventing the inflow of contrast medium into the duodenum, and the presence of air within the ducts. Additional sources of error are the end of the polythene catheter or the limbs of the T-tube, which may simulate a stone by pressure against the wall of ducts or when they are viewed on end. Space does not permit a discussion of certain simple precautions that will prevent these errors.

In addition to the false-positive cholangiograms, one may have false-negative results, in which small stones are masked by the contrast agent. This occurred in nine of our patients (2%). In eight instances, the stones measured 5 mm. or less. They were demonstrated by subsequent exploration or delayed cholangiography It is reasonable to conclude that this 2% represents a minimum figure for false-negative results, since certain undetected stones, masked by the contrast medium, undoubtedly later pass into the intestine

As with any technical procedure, certain complications may be anticipated These include a mild, transient low-grade fever during the immediate postoperative period, presumably due to regurgitation of the medium into the blood stream, and a transitory elevation of the serum amylase level, possibly correlated with the not infrequent reflux into the pancreatic duct Some degree of extravasation occurred in 13% without apparent untoward effects

Comment

From the review of our data it is apparent that satisfactory results can be obtained with operative cholangiography by careful attention to certain technical details The widespread use of delayed cholangiography after surgical exploration and T-tube decompression of the common duct indicates that the principle of radiologic confirmation of the absence of stones within the ducts is generally accepted

Those surgeons who employ delayed cholangiography but rarely use operative cholangiography must agree with the principle of operative cholangiography but avoid the procedure because of dissatisfaction due to errors in technique and interpretation With increased care in technical performance, these errors can be reduced and the procedure should come into wider use

Summary

We have performed operative cholangiography in 444 patients subjected to biliary tract surgery, with a diagnostic accuracy of 88% Stones missed on operative exploration were detected by operative cholangiography in 36 patients Reasons for the unsatisfactory results include poor technique and false-negative and false-positive cholangiograms Increased attention to details of technical performance is necessary With the resultant improvement in operative cholangiograms, there should be more widespread use of the method

DISAPPEARANCE OF "STONE" SHADOWS IN POSTOPERATIVE CHOLANGIOGRAMS

Warren H Cole, M D
and
William H Harridge, M D, Chicago

During the past seven years we have encountered nine patients in the Illinois Research and Educational Hospitals who after cholecystectomy and choledochostomy had residual "stones" in the common duct as determined by cholangiography All except one of these had been operated on in our own hospital Under conservative treatment, consisting of prolonged T-tube drainage and administration of bile salts (3 to 4 Gm per day in divided doses), dissolution, disintegration, or passage of these "stones" was observed in seven of the nine cases We should add that we have no proof that these shadows represent stones, all we can say is that they resemble those cast by stones

• *The possibility that stones in the common bile duct may disappear during conservative treatment with 3 to 4 Gm of bile salts per day by mouth is illustrated by the histories of nine patients selected from a larger series of patients who have undergone cholecystectomy and choledochostomy with insertion of a T tube in the common duct The nine patients constituted a group in whom postoperative cholangiography gave evidence of retained or recurrent stones and in whom obstruction of bile flow was incomplete so that the T-tube could be clamped all the time In seven of these patients, the "stone" shadows vanished in 8 to 13 weeks In two, the shadows persisted, and stones were removed at a subsequent operation Proof that the shadows represented stones and that the administration of bile salts played a decisive part in their disappearance was not absolute, and the question whether the stones disintegrated, dissolved, or passed unchanged was not settled, but significant evidence relating to these problems was obtained*

From the Department of Surgery, University of Illinois, College of Medicine, and the Illinois Research and Educational Hospitals

Read in the Panel Discussion on Common Duct Stones before the Section on Surgery, General and Abdominal, at the 105th Annual Meeting of the American Medical Association, Chicago, June 14, 1956

Evidence Supporting Theory of Dissolution or Disintegration of Stones

In addition to the clinical data presented herein, we wish to present other evidence supporting the possibility that the stones dissolved or disintegrated. The fact that the "stone" shadows disappeared rapidly rather than by slow decrease in size suggests that the stones disintegrated rather than dissolved, unless they were passed through the sphincter of Oddi. Most of the shadows were so large that it hardly seems possible that the stones could have been passed. Disintegration might take place by dissolution of the outer "hard" portion and of the matrix holding the cholesterol together, in this case, they might crumble and be passed as granular debris. All surgeons have seen many stones so soft that they broke into amorphous fragments as they were removed from the common duct. It is barely possible that a disturbance in the cholesterol-bile salt ratio, as suggested years ago by Andrews,[1] might exert a prominent influence in the "dissolution."

It is a well-known fact that, if gallstones from humans are placed in the gallbladder of a dog, the stones will disappear in a few weeks or months. It is rather obvious that this disappearance is related to dissolution and not to passage through the small cystic duct of the dog. The increased bile salt content in the dog's bile, as reported by Sobotka[2] and others, could readily explain this disappearance by dissolution in the dog.

The great variation in the percentage of common ducts explored, as noted in the literature, offers fairly good evidence that a huge number of stones in the common duct are passed or dissolve. McKittrick and Wilson[3] report the performance of cholecystectomy and choledochostomy in 100 consecutive patients with stones in the gallbladder, with stones found in the common duct in 52%. Cattell[4] reports exploration of the duct in 45.7% of 1,104 patients having cholecystectomy, with stones found in 16.8% of the entire group. On the other hand, Glenn[5] reports opening the common duct in only 10.5% of 2,472 patients having cholecystectomy, with the finding of stones in only 7.2% of the entire group. Recognizing the vast difference in discovery of stones, as listed above, Glenn followed up 100 consecutive patients who had undergone cholecystectomy performed by his group more than 10 years previous to his study. Of these 100 patients, 93 were asymptomatic, 7 had symptoms leading to common duct exploration, but stones were found in only 4 of these. If we add this 4% to Glenn's original figure of 7.2, we obtain a figure of only 11.2%, which is still below Cattell's figure of 16.8%. It appears that the stones were probably present in many of Glenn's patients not having a common duct exploration. If so, they must have been passed or "dissolved."

One might ask the question, why should stones disintegrate in the common duct after cholecystectomy, whereas they grow and perhaps occasionally form in the common duct of patients not having had their gallbladder removed? There may be a possible explanation in the fact that, with the gallbladder in place, a certain amount of concentration of bile takes place, although this is less so in diseased gallbladders. If concentrated bile is expelled from the gallbladder, flowing over stones in the common duct, one might expect growth of the stone and not dissolution, particularly if the diseased gallbladder absorbs bile salts, with disturbance of the bile salt-cholesterol ratio, as claimed by Andrews.[1]

If disintegration of stones does take place in the common duct after cholecystectomy, one would not expect it in patients having complete obstruction of the duct, because the possible effect of dissolution by constant flow would be obliterated. In all seven of our patients in whom there was disappearance of the "stone" shadow we were able to clamp the T-tube constantly, although in two patients jaundice persisted for a prolonged period, in one patient, clamping of the T-tube was associated with leakage of considerable amounts of bile around the T-tube.

Findings in Seven Patients in Whom Stone Shadows Disappeared

	Surgery			No of Wk Postoperatively for Cholangiogram				No of Wk Postoperatively Bile Salt Therapy Begun

Analysis of Cases

As stated, during the last seven years we have found "stone" shadows in the postoperative cholangiograms of nine patients in our hospital who have had cholecystectomy and choledochostomy. In seven, the shadows disappeared, but in two, in whom the T-tube was kept in place for a year, the shadows remained, operation was performed on these two patients after this interval, and stones were found in the common duct. We advised operation in one patient at the end of six months, but he declined because of urgent business, in the other patient operation was delayed because the patient was lost to follow-up and did not return. Treatment in all cases was confined to the oral administration of bile salts (3 to 4 Gm per day in divided doses) and constant clamping of the T-tube. We would not attempt this treatment if the duct were completely obstructed.

The table reveals the important data for each patient as related to operation, cholangiograms, and therapy. The history and other clinical findings are given in the case reports, below In all cases the shadow or deformity was demonstrable in more than one film Several cholangiograms in other patients, not reported on, revealed deformities, but in most cases a diagnosis of air bubbles could be made quite readily In two others, the shadows were doubtful and were absent in a subsequent cholangiogram These, too, might have been stones, but we did not include them since there was definite doubt about the identity of the shadows The time required before a normal cholangiogram was secured was 25, 21, 15, 31, 7, 15, and 8 weeks respectively The shadow might have been absent at an earlier date, but we made no attempt to obtain weekly cholangiograms At least we know that the shadow persisted through 16, 12, 12, 18, and 10 weeks, respectively, in five of the seven patients In two of the patients the "stone" shadows were present in four and three different cholangiograms, respectively, spaced three to seven weeks apart

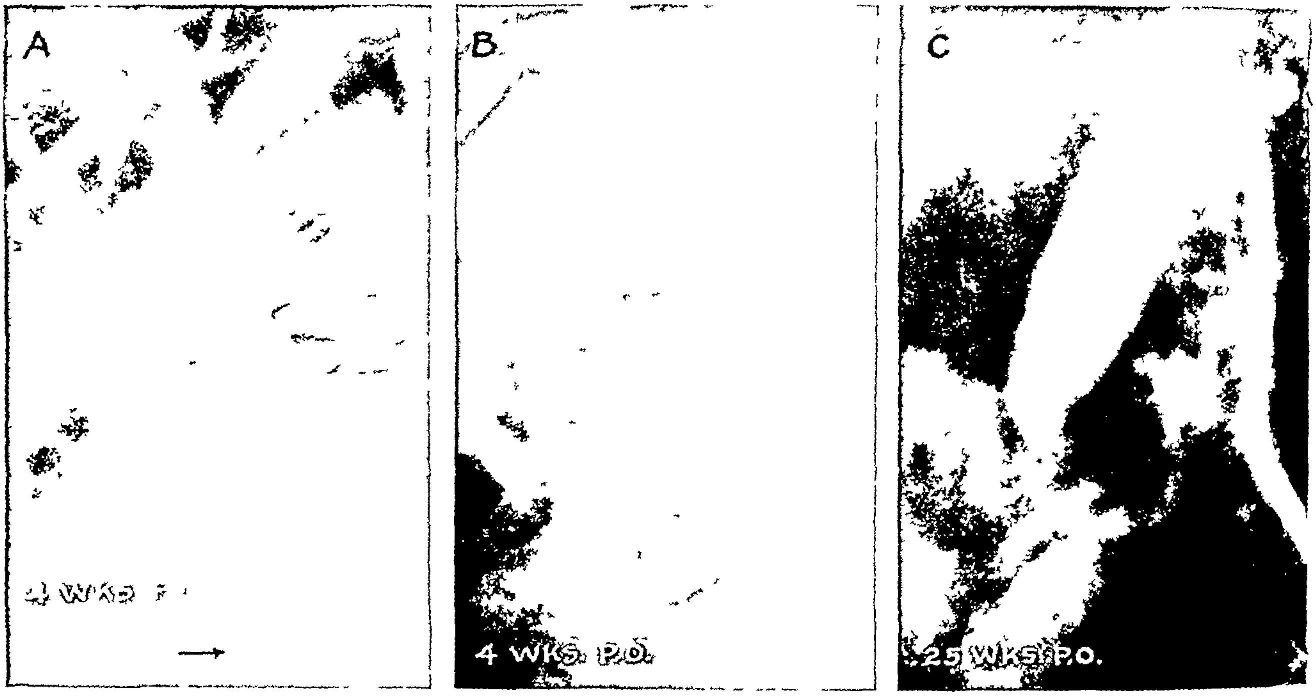

Fig 1 (case 1) —*A* and *B*, different views of cholangiogram (four weeks postoperatively), revealing "stone" at ampulla Later cholangiograms taken 9 and 16 weeks postoperatively (not shown here) confirmed presence of stone but revealed slight decrease in common duct size and better drainage of dye into duodenum *C*, normal cholangiogram, taken 25 weeks after operation

Obviously, we cannot prove that the shadows revealed in the cholangiograms were stones However, since the deformity was present in more than one film in all cases and fulfilled the roentgenographic requirements for stones, we feel the diagnosis of stone was justified Perhaps the most diagnostic shadows are those with irregular shape and surface surrounded completely by iodopyracet (Diodrast) compound A concave shape on the terminal end of the cholangiographic shadow is considered fairly conclusive of stone

Although we gave bile salts (3 to 4 Gm per day in divided doses) to all patients, we have no evidence whatsoever that this drug played a vital role in the disappearance of the shadows However, we are sufficiently convinced of its efficacy that we gave it to all, and we will continue to do so until we have evidence to the contrary It is true that, in two cases, bile salt therapy was short (see last column in the table)

We have additional evidence that all seven patients had stones in the common duct, inasmuch as five had jaundice at the time of operation and two had a history of jaundice It is also very significant that in three of the seven patients no stones were found in the common duct at the time of choledochostomy, two of these three had jaundice at the time of operation and the third had a history of jaundice Because of lack of space the cholangiograms of only three of the patients are reproduced here

Report of Cases

Case 1 —A 56-year-old woman came to the hospital in June, 1955, complaining of recurrent attacks of pain in the right upper quadrant with jaundice However, at the time of admission she did not have jaundice and had not had any pain for two or three weeks She was operated on on June 15, 1955 The gallbladder contained numerous stones and was buried rather deeply in the liver The cystic duct was large in diameter but short The common duct was explored with a common duct scoop, but no stones were found The scoop passed through the sphincter of Oddi without difficulty A cholangiogram, performed while the patient was on the table, revealed no shadows suggestive of stones, iodopyracet entered the duodenum readily Accordingly, it was assumed (probably erroneously) that the stone causing the attacks of jaundice might have passed through the sphincter of Oddi into the duodenum The common duct was closed around a T-tube and the wound closed A postoperative cholangiogram was taken July 12, 1955 (four weeks postoperatively) There was moderate dilatation of the common duct, and a shadow typical of that of a stone was noted at the ampulla of the common duct (fig 1) In spite of the obstruction noted on the x-ray, apparently bile did pass into the duodenum readily, because the T-tube was clamped almost continuously after June 27, 1955 In August, the patient was placed on bile salt therapy, receiving 1 Gm four times a day Cholangiograms taken Aug 19 and Oct 10, 1955, revealed an obstruction similar to the one noted on July 12 However, the cholangiogram taken Dec 6, 1955 (25 weeks postoperatively), revealed no obstruction, and iodopyracet entered the duodenum readily The T-tube was removed Dec 14, 1955 When last seen, six months later, the patient was asymptomatic and had no pain or recurrence of jaundice

CASE 2 —A 48-year-old woman with diabetes was admitted in early June, 1949, complaining primarily of vomiting and slight abdominal distress However, shortly after admission, she developed severe pain in the right upper quadrant and jaundice The icterus index was 18 and the bilirubin level 2 mg per 100 cc On June 14, 1949, she had a cholecystectomy and common duct exploration The gallbladder was inflamed and contained many stones The common duct contained 50 to 75 stones varying from 2 to 5 mm in diameter There were also several stones in the right and left hepatic ducts A lead probe passed readily into the duodenum A cholangiogram performed Aug 10 1949 (seven weeks postoperatively), revealed several small filling defects in the terminal end of the common duct, although the iodopyracet passed readily into the duodenum Another cholangiogram, taken Sept 12 1949, revealed slight narrowing at the distal end of the common duct and a probable partial obstruction, the filling defects were still present, but not so prominently as in the previous film After June 25, the T-tube was clamped most of the time However there appeared to be definite obstruction, because by Sept 30 the patient still had slight jaundice and complained of pruritus, along with alternating cholic and acholic stools On Oct 5 she was placed on therapy with 1 Gm of bile salts four times a day The cholangiogram taken Nov 17, 1949 (21 weeks postoperatively), revealed a widened common duct, but the stone shadows were gone The T-tube was removed early in December, 1949 When last seen, in August, 1955, the patient was well and had had no difficulty since the T-tube had been removed

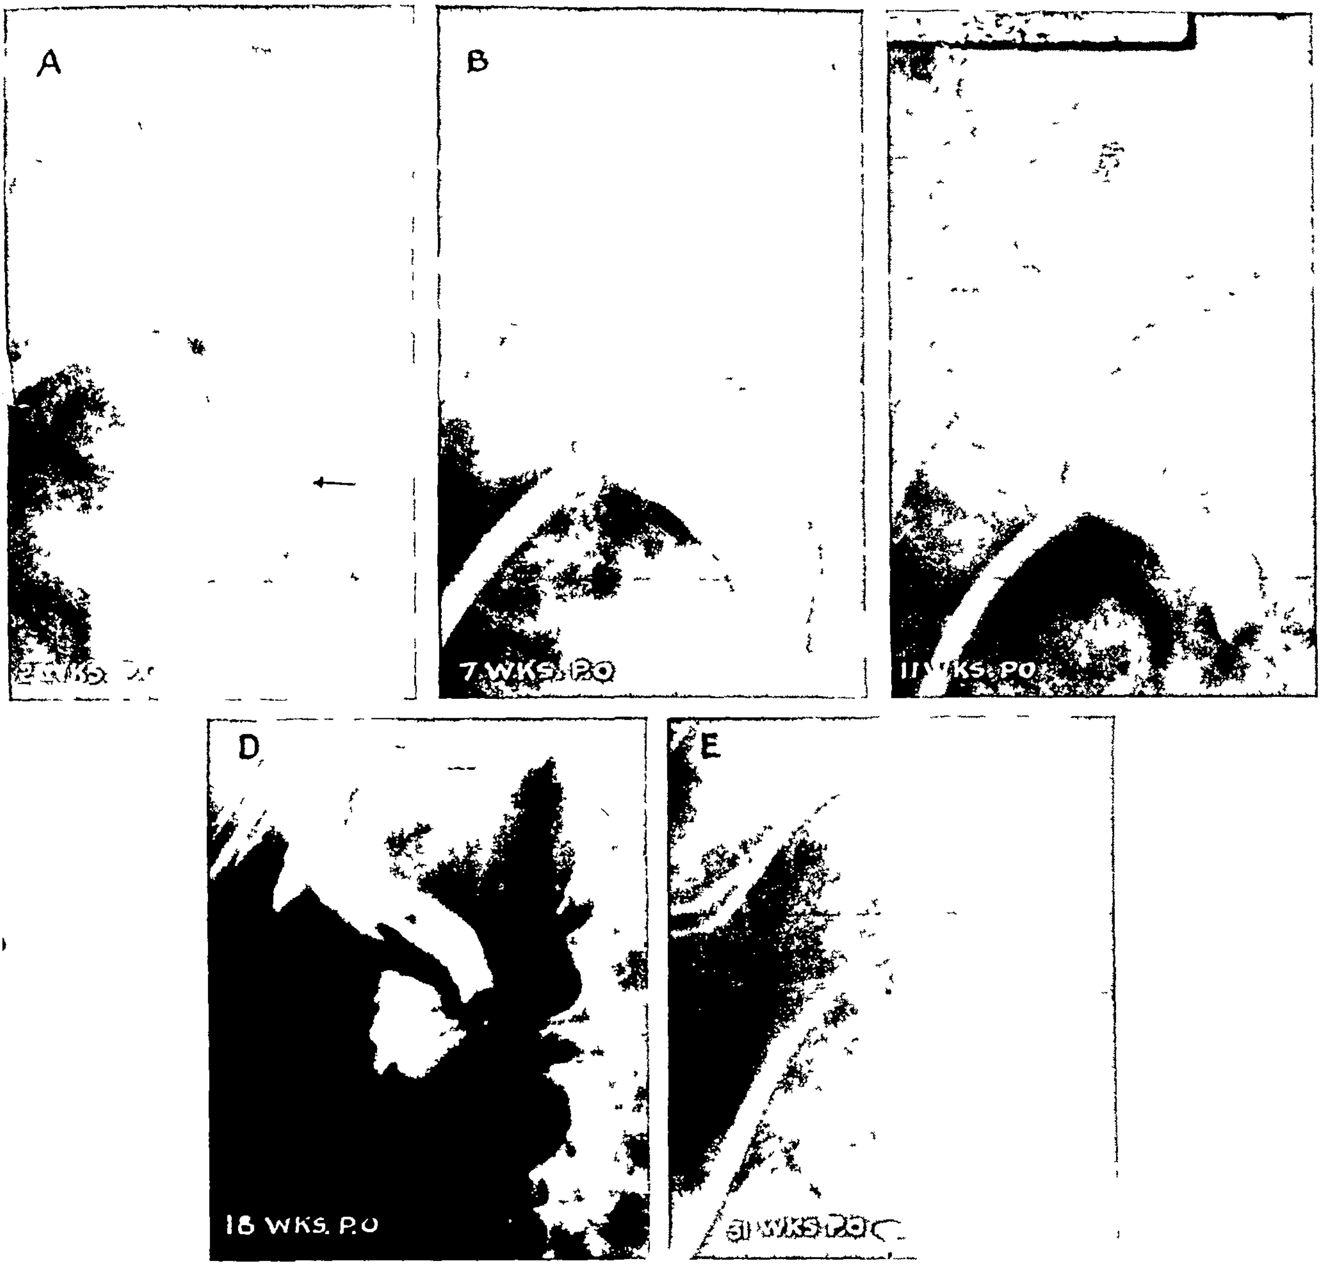

Fig 2 (case 4) —Cholangiograms taken, *A*, 2, *B*, 7, *C*, 11, and, *D*, 18 weeks postoperatively, revealing 'stone' in distal common duct with resultant partial obstruction and dilatation *E* normal cholangiogram, taken 31 weeks postoperatively

CASE 3 —A 52-year-old woman was admitted Dec 20, 1951 Five weeks before admission she had developed sudden pain in the right upper quadrant radiating to the right subscapular area Within a few days this pain was followed by jaundice, pruritus, acholic stools, and dark urine The jaundice and acholic stools persisted up to time of admission and date of operation The icterus index was 104 and the bilirubin content of the blood was 15 5 mg per 100 cc On Jan 7, 1952, she had a cholecystectomy and common duct exploration The common duct appeared to be blocked about 1 cm from the ampulla of Vater but no stone was found through the opening in the common duct Accordingly, we opened the duodenum to investigate the cause of the obstruction The duodenal papilla was very small and we were not sure that we actually identified it We opened into the common duct at a point where the common duct lay immediately adjacent to the duodenal wall as determined by proximity of the probe in the duct We then probed the common duct upward from the papilla However we found an obstruction at a distance of 2 cm that would not allow passage of a 6-mm scoop This stenosis was located in the head of the pancreas and may have been due to pancreatitis,

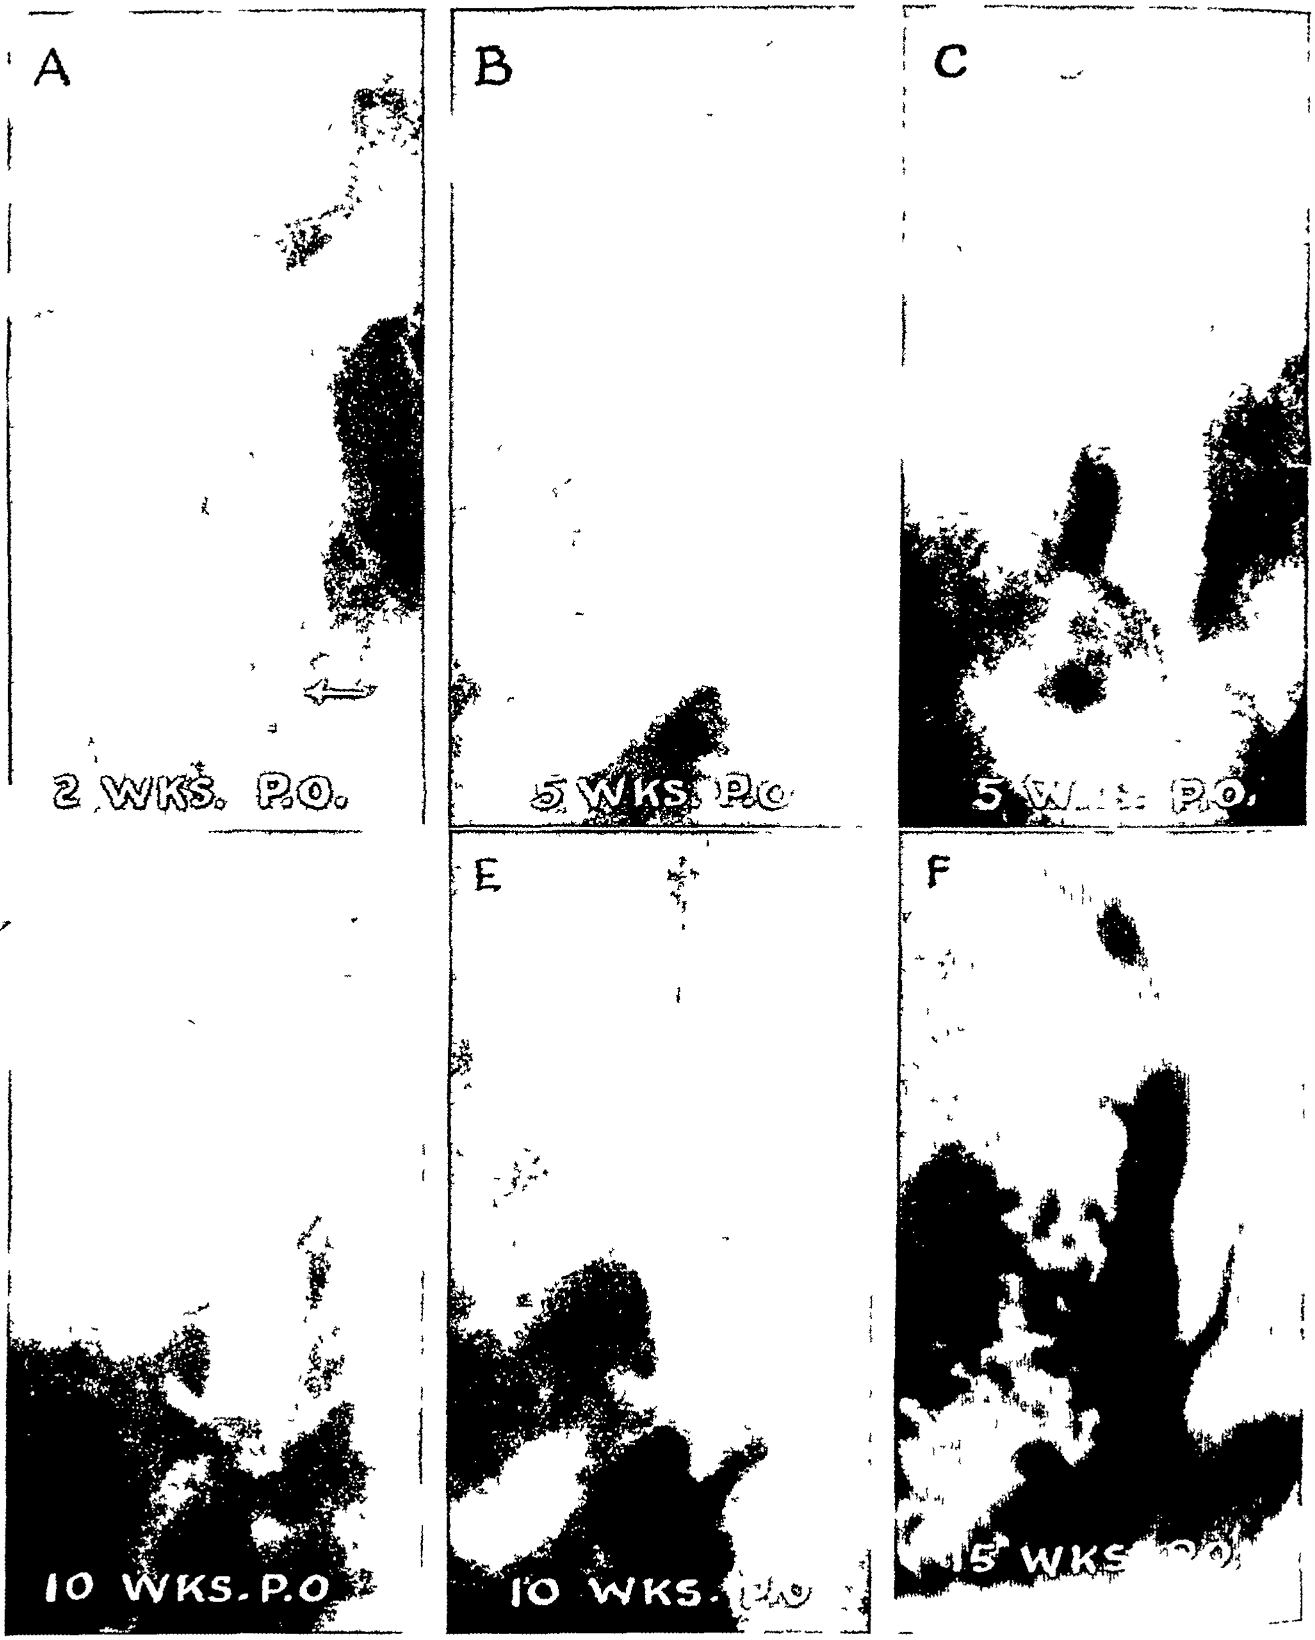

Fig 3 (case 6) —Cholangiograms taken *A*, 2, *B* and *C*, 5 and, *D* and *E*, 10 weeks postoperatively, revealing constant filling defect with incomplete obstruction *F*, normal cholangiogram taken 15 weeks postoperatively although there was very little enlargement or induration of the head of the pancreas In spite of prolonged manipulation, we were unable to find a stone that could explain the jaundice On March 26, 1952 (11 weeks postoperatively), a cholangiogram was taken A circular filling defect was noted in the distal end of the common duct, with a very small amount of opaque material passing into the duodenum around it The film taken one hour later still showed marked retention of dye in the biliary tree, indicating that considerable obstruction existed Another cholangiogram taken April 2 revealed a similar filling defect, and only a small amount of dye entered the duodenum The patient was placed on therapy with 1 Gm of bile salts four times a day, beginning April 2 A cholangiogram taken April 23, 1955, revealed absence of the stone shadow, and the iodopyracet flowed into the duodenum readily It appeared that the major obstruction was now gone, but there was distinct narrowing of the common duct 2 cm from the sphincter of Oddi Although there no longer appeared to be obstruction of the common duct we left the T-tube in place because of its narrowing Cholangiograms taken May 7 and June 11, 1952 revealed no obstruction, but the narrowing was still present Another cholangiogram, taken July 23, revealed the same findings The T-tube was removed July 23 When last heard from, on Sept 20, 1955, the patient said she had had no trouble since removal of the T-tube

Case 4 –A 68-year-old man was admitted to the hospital on Oct 28, 1954, with lower abdominal distress associated with constipation of two years duration About three weeks prior to admission he developed severe epigastric pain, with vomiting, chills, and a temperature of 104 F (40 C) The next day he noted that he had jaundice and that his urine was dark and his stools acholic This attack gradually subsided, so that, at the time of admission, he had only slight jaundice However, a few days after admission the pain, vomiting, and fever recurred along with deep jaundice On Nov 12 1954, he had a cholecystectomy and common duct exploration The gallbladder was small and shrunken The common duct was dilated to a diameter of 4 cm and contained two mulberry stones The probe entered the duodenum with ease A cholangiogram taken Nov 26 (two weeks postoperatively) revealed a radiolucent shadow suggestive of a stone at the distal end of the common duct The common duct was dilated proximal to this shadow (fig 2) There was further evidence of obstruction in that when the tube was clamped two weeks after operation, bile leaked around it to the exterior The patient was placed on therapy with bile salts on Nov 21, 1954 Cholangiograms performed on Jan 5, Feb 9, and March 30, 1955, revealed findings similar to those of Nov 26 However, a cholangiogram performed June 15, 1955 (31 weeks postoperatively), revealed no evidence of stones, the common duct was of normal size and the iodopyracet entered the duodenum readily The T-tube was removed June 15 1955 When last seen, in September, 1955, the patient was asymptomatic

Case 5 –A 59-year-old woman entered the hospital Dec 29, 1952, complaining of flatulence, dyspepsia, and fatty-food intolerance of six months duration Ten days before admission she developed jaundice and had dark urine, although the stools were not acholic The pain was variable On Jan 5, 1953, the patient had a cholecystectomy and common duct exploration There were many stones in the gallbladder and common duct Because the probe would not enter the duodenum, it was opened over the duodenal papilla A sphincterotomy was performed, since the opening through the sphincter was no more than 1 or 2 mm in diameter A cholangiogram, done while the patient was on the operating table, was undiagnostic, since the ducts filled and the iodopyracet entered the duodenum However, a cholangiogram done on Jan 14, 1953 (two weeks postoperatively), revealed a constant filling defect that appeared to obstruct the flow of iodopyracet into the duodenum almost completely Therapy with 1 Gm of bile salts four times a day was started on Jan 23, 1953 Cholangiograms performed Feb 24 and March 11 1953, were normal The T-tube was removed March 11, 1953 When last heard from, on May 25, 1955, the patient was asymptomatic and had been so since the T-tube had been removed

Case 6 –A 50-year-old man was admitted to the hospital in July, 1954, with a history of severe epigastric pain, chills, fever, and slight jaundice over a period of four or five days, two weeks before admission The serum amylase level was elevated during this attack, being above 1 000 units per 100 cc on one occasion On his second admission, the patient was asymptomatic and no jaundice was present At operation, stones were found in a badly diseased gallbladder The head and most of the body of the pancreas were indurated and enlarged to at least two times the normal size Stones and much bile precipitate were present in the common duct The stones and precipitate were removed and a cholecystectomy performed a T-tube was inserted in the common duct Cholangiograms taken 2, 5 and 10 weeks after operation revealed constant filling defects (fig 3) However when the T-tube was clamped there was no pain or significant leak of bile The patient was on bile salt therapy from the 2nd to the 15th week after operation The cholangiogram taken 15 weeks after operation was normal, and the T-tube was removed The patient has been completely asymptomatic up to the time of writing

Case 7 –A 50 year old woman was admitted to the hospital on Jan 26, 1954 Three weeks previously she had developed severe right subcostal pain, followed in a few days by jaundice acholic stools, and dark urine On the patient's admission, the bilirubin content of the blood was 3 mg per 100 cc On Jan 29 1954, she had a cholecystectomy and common duct exploration No stones were found in the common duct A probe passed through the sphincter of Oddi, but with moderate difficulty A cholangiogram taken Feb 17, 1954, revealed a radiolucent defect in the common duct about 2 cm distal to the exit of the T-tube This was diagnosed as a stone Treatment with 1 Gm of bile salts four times a day was started at this time Cholangiograms taken March 29 1954, were normal and the T-tube was removed The patient has been asymptomatic since that date

Summary

During the past seven years we have encountered nine patients in the Illinois Research and Educational Hospitals who, after cholecystectomy and choledochostomy, had residual 'stones' in the common duct as determined by cholangiography All except one of these patients had been operated on in our hospital All of these patients were treated conservatively for several months, treatment consisted of administration of 3 to 4 Gm of bile salts per day by mouth in divided doses and continuous clamping of the T-tube The "stone" shadows disappeared in seven of the nine patients in 8 to 31 weeks, in the two patients in whom the shadows persisted, operation was performed and the stones removed In all patients the obstruction was incomplete, allowing clamping of the T-tube with flow of bile through the duct all the time We would not expect this therapy to be successful if the T-tube could not be clamped, and would not try it We have no proof that these shadows represented stones All we can say is that they were suggestive of stones, and, on six or seven previous occasions when residual stones were diagnosed by cholangiography, we found stones at operation in every case

PRESENT STATUS OF COBALT-60 TELETHERAPY IN THE MANAGEMENT OF THE CANCER PATIENT

Gilbert H Fletcher, M D, Houston, Texas

• *Cobalt 60 teletherapy is essentially a form of supervoltage radiation There is no specificity of action on cancers by the various modalities of supervoltage, and it is a misconception to suppose that Co ^{60} teletherapy has something to offer when 2-million volt x ray therapy has not Both offer the possibility of increasing the dosage of radiation to tumors because of better skin tolerance and a slight increase in tolerance of the deeper structures But both must be used with due regard to the possible later appearance of subcutaneous and deep muscle fibrosis and other signs of cumulative damage, and the curability of a tumor is one of its fundamental biological properties Supervoltage or Co ^{60} teletherapy is not indicated in a number of conditions, e g, lymphomas in areas of superficial lymph nodes Its use is elective in a number of other conditions, e g, mediastinal and retroperitoneal lymphomas Its use is imperative in a considerable number of conditions, including cancers of the oropharynx and urinary bladder and late cancers of the cervix and vagina It has technical advantages that need to be explored further, but an objective and unemotional approach is necessary*

The very rapid progress of atomic and nuclear physics in the last decade has resulted in new modalities of delivering radiation High-energy generators, producing either x-rays or accelerated particles, and gamma ray–emitting isotopes, such as radioactive cobalt (Co ^{60}) and cesium (Cs ^{137}), have made possible a whole range of supervoltage (from 1 to 3 million volts) and megavoltage (above 10 million volts) equipment It is unavoidable that misconceptions, unfounded hopes, and confusion will arise not only among physicians but in the public due to the extensive interest of the lay magazines in all matters pertaining to what is now called nuclear medicine The specialist himself has difficulty in assessing the clinical value of these newly developed tools

The increase of the number of deaths from cancer, due to the longer life span and the diminished incidence of deaths from other causes, is a factor in the greater awareness of cancer generally and motivates the intensified interest in all forms of cancer therapy The physical and psychological trauma caused by the protracted length of the terminal stage in many cases of cancer produces conditions favorable for an emotional approach to any new development that arouses "last-straw hopes

General practitioners, internists, and almost all the gical specialists are connected with the manage- t of cancer patients On these physicians rests the nsibility of referring the patient to a skilled and operly equipped specialist or institution Their role has a wide scope, as, in addition, they must advise the patients families and be prepared to comment on the medical information that nowadays reaches the lay public It is, therefore, essential that physicians have a background of factual knowledge about all the uses of radioactivity in the treatment of cancer, with special emphasis on their clinical usefulness or limitations

Co ^{60} teletherapy is essentially a form of supervoltage radiation The first million-volt machines were put into clinical use in the early 1930's In other words, supervoltage radiation therapy is over 20 years old The years preceding World War II saw further technological developments but it was mostly during and after World War II that the tremendous expansion of atomic and nuclear physics brought about varied and powerful supervoltage and megavoltage devices, including the production, in the atomic reactors, of gamma ray–emitting isotopes with high specific activity, which can be used for external-beam therapy

Among those gamma ray–emitting isotopes, Co ^{60} is perhaps the most suitable for use in irradiators, which are, for all practical purposes, identical to 2-to 3 million-volt x-ray generators The physical characteristics of the beam of a kilocurie teletherapy irradiator are essentially the same as those of the beam of the x-ray generators, and, therefore, the biological and clinical advantages in the treatment of human cancers are the same The costs of production and maintenance of equipment may be less, but these factors have no bearing on the clinical effectiveness This similarity of the beams is an important point, as it should dispel the rather widespread misconception that Co ^{60} teletherapy or Cs ^{137} teletherapy has any specific action in the treatment of human cancers

Co ^{60} irradiators have been in clinical use for only four years, and most of the discussion that will follow is based on the longer experience with supervoltage radiation therapy A review of the physical characteristics of supervoltage radiation and the fundamental principles underlying radiation therapy must be made prior to the discussion of the clinical advantages and indications in the various anatomic sites

Physical Characteristics of Supervoltage Radiation

The following physical characteristics of million volt x-ray beams are pertinent to the treatment of human cancers 1 The moist desquamation of the skin, which is inevitable at 200 kv, the level at which doses adequate for control of deeply located cancers are delivered, can be avoided 2 The radiant energy

---

From the Department of Radiotherapy, University of Texas M D Anderson Hospital and Tumor Institute

Read before the Section on Radiology at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956

is not dispersed sideways outside of the beam, and, therefore, adjacent structures receive less radiation In addition, the body as a whole absorbs less radiant energy, and, consequently, there is less systemic reaction, such as x-ray sickness, drop in blood cell count, or general fatigue 3 A greater percentage of the energy reaches the deep-seated organs, and, therefore, it is possible to deliver larger doses to cancers in these organs 4 There is less absorption by bone, which can be significant if there are bony structures between the surface of the body and the tumor to be treated, and, therefore, there is less risk of late osteonecrosis All these characteristics are additive—to the effect that the physician can deliver greater tumor doses with less skin reaction, less systemic discomfort, and, up to a point, a better deep organ tolerance

Radiation of any kind (x-ray, gamma rays, and accelerated particles, such as electrons, protons, and alpha particles) always act through the same physical phenomena of ionization and excitation These physical phenomena at the level of the atomic structure are responsible for the chemical changes that, in turn, are responsible for the biological changes that produce damage to all living cells There is, at times, irreversible damage, making possible the sterilization of cancers There are slight quantitative differences in the biological effectiveness of the different forms of radiation Extensive physical and biological studies have demonstrated this difference to be from 10 to 15% more for the million-volt range than for the 200 kv range This difference is not specific for cancer cells but applies to all living cells In practice, this means that, if, in order to sterilize a tumor, a tumor dose of 5,000 r in five weeks is necessary with 200 kv radiation, 5,500 6,000 r is necessary with supervoltage radiation

Principles Underlying Radiation Therapy

Radiation therapy of human cancers is possible because some types of cancer have a greater sensitivity than the normal supporting structures This margin of tolerance varies depending on the type of tumor and on the organ from which the tumor arises This margin is usually very narrow Tumor cells themselves are not affected differently by supervoltage radiation, but the deep-organ tolerance is somewhat increased, and, therefore, greater tumor doses are possible For instance, in the treatment of tumors of the urinary bladder, 6,000 r in five weeks can be delivered to the whole bladder with supervoltage radiation without reactions unbearable to the patient, whereas 5,000 r cannot be delivered safely and without excessive discomfort to the patient in the same period of time using the 200-kv equipment Therefore, in this instance, there is a positive balance that is demonstrated by improved clinical results The same holds true for irradiation of the whole pelvis in the late stages of cancer of the cervix and also for irradiation of the posterior third of the oral cavity and pharynx

There is no specificity of action of supervoltage radiation on tumor cells as compared with radiation of 200 kv, tumors that are normally radioresistant to medium voltage will stay resistant to supervoltage For instance, melanomas, glioblastomata multiformeia, soft tissue sarcomas, and, by and large, the adenocarcinomas originating in the gastrointestinal tract are not benefited by supervoltage therapy There are exceptions For instance, the adenocarcinomas of the rectum that have some degree of radioresponse can at times be controlled with supervoltage radiation because much higher doses can be delivered This can be put to advantage in inoperable tumors, or local recurrences This form of therapy is not an alternate method for the classic abdominoperineal resection, which should be performed whenever possible It is evident that the ability to deliver larger tumor doses is of most use in the treatment of those tumors that are moderately radiosensitive, such as the keratinizing epidermoid carcinomas and those that are located in areas inaccessible to the eminently effective interstitial or intracavitary radium therapy or in areas not directly available to low-voltage or medium-voltage radiation

Larger volumes of tissue can tolerate only smaller doses of radiation Recovery from the radiant energy comes from the surrounding undamaged structures, particularly blood vessels The situation is very similar to the healing of wounds or burns, and recovery becomes slower and even impossible if large areas are overirradiated Therefore, if the cancer is very extensive and the volume necessary to encompass the whole tumor is very large, the dose must be less if irreversible damage to vital structures is to be avoided Unfortunately, the chance for permanent control decreases At times, if a long-lasting control rather than a permanent cure is desirable, only part of the known tumor can be included in the beam in order to deliver sufficiently high doses For instance, if the aim of treatment is to reopen the lumen in cancer of the esophagus and preserve this lumen until death occurs from distant metastases, one must limit the irradiation to the visibly obstructing part of the cancer

The treatment of cancers with radiation is not different from the surgical approach Instead of removing en bloc the volume of tissue that contains all tumor cells, one must deliver high doses of radiation to the same volume in order to sterilize all tumor cells In the same way that surgery is limited by the problem of the removal of part or all of some vital structures, the necessarily high tumor doses are limited by irreversible damage incompatible with life

When the cancer is too extensive or even more generalized, there is, of course, no form of radiation, irrespective of the modality and voltage, that can appreciably affect the course of the disease However, radiation may be used for relief of one specific local symptom, oftentimes producing great benefit to the patient The advantages of supervoltage radiation cannot be measured only by improved cure rates, with five-year survival being the criterion The temporary control of distressing symptoms is very beneficial even if it does not prolong life These clinical benefits can rarely be expressed in statistics

In mentioning the advantages of supervoltage radiation, one tends to overlook the fact that its use is accompanied by limitations and late sequelae It takes years for the subcutaneous and deep muscle fibrosis to set in after heavy radiation treatment The absence of acute skin reaction is very conducive to overenthusiasm and radical treatment In addition, the skin-sparing effect tends to encourage the use of supervoltage radiation for the treatment of recurrences after previous radiation This can be carried without any appreciable skin reaction but unfortunately the previous damage to the inner structures, which never subsides, oftentimes causes exceedingly painful radionecrosis It is only in rare circumstances, and with great conservatism that re-treatments can be performed without excessive risks

In many ways, the development of new radiotherapeutic tools and in particular supervoltage radiation can be compared with the advances in surgery and anesthesiology that have made possible more radical and, therefore at times more effective procedures, resulting in appreciable clinical progress They are not, however, a revolutionary approach Greater skill and more clinical experience are necessary to adapt these powerful tools to the natural history of the disease processes with which one is trying to interfere By and large, increased clinical benefits may be derived from supervoltage or Co^{60} teletherapy in the area of those cancers that are neither radioresistant nor generalized when first seen and that, therefore one can hope to control or cure

Usefulness of Cobalt 60 Teletherapy in Various Tumors

Not Indicated	Elective	Imperative	Special Studies Desirable
Head and neck	Esophagus	Extensive tumors of anterior ⅔ of oral cavity	Preoperative x ray therapy for breast cancer
Skin and lip	Mediastinal and retroperitoneal lymphomas	All tumors of Posterior ⅓ of oral cavity (fauces tonsils base of tongue soft palate)	Some rectal cancers
Anterior ⅔ of oral cavity (early)	Seminomas	Paranasal sinuses	Some thyroid cancers
Vocal cord (early)	Occasionally bronchogenic carcinoma	Oropharynx and hypopharynx	Miscellaneous tumors
Nasopharynx with no involvement of base of skull	Ovarian cancers (localized to pelvis)	Extrinsic tumors of larynx	Locations where skin must be spared (metastases to pelvic bones)
Early cancers of cervix and vagina (intracavitary radium therapy)		Inoperable neck nodes (postoperative recurrences)	
Postoperative breast irradiation		Late cancers of cervix and vagina	
Lymphomas in areas of superficial lymph nodes		Epidermoid carcinoma of	
Bony metastasis		Female urethra	
		Urinary bladder	
		Embryonal carcinoma of testis	

In the epidermoid carcinomas accessible to low-voltage or medium-voltage therapy, such as cancers of the skin and lip, and in those epidermoid carcinomas optimally treated by interstitial or intracavitary radium therapy, such as the early cancers of the anterior two-thirds of the oral cavity or those of the uterine cervix, supervoltage therapy has nothing to offer and its use would even be a retrograde step A review of the various anatomic sites and a discussion of the sites in which particular tumors can be handled best with supervoltage radiation (see table) are in order

Sites of Tumors and Radiation Therapy

Head and Neck—Early epidermoid carcinoma of the anterior two-thirds of the oral cavity is still best handled by conventional means of interstitial radium therapy In contradistinction, satisfactory results are not obtained in extensive tumors, and, if radical surgery is not indicated, supervoltage therapy offers a chance for more permanent cures or, at any rate, better growth restraint

Even in the early epidermoid carcinoma of the posterior third of the oral cavity and oropharynx, results are unsatisfactory with conventional means of therapy It is already a well-established clinical fact that supervoltage radiation offers a better chance for local control in this group of carcinomas In addition to better control of the primary lesion, more adequate handling of the often-present metastatic nodes is possible with supervoltage therapy, especially in combination with radical neck dissection In radical neck dissection after Co^{60} teletherapy, there is not nearly as much danger of delayed wound healing

With rare exceptions, the epidermoid carcinoma of the paranasal sinuses is rarely cured by radiation alone or by surgery alone The combination of the two offers a better chance of control Here too, postoperative radiation delivered with Co^{60} can give a better distribution of the radiation and a higher tumor dose

Supervoltage radiation also offers the possibility of control and possible cure in malignant tumors of the parotid gland—either primary adenocarcinoma, myoepithelial tumor, or metastases to the lymphatics of the parotid gland from epidermoid carcinoma Here at times surgery followed by radiation is beneficial

Inoperable metastatic nodes in the neck and postsurgical recurrences require high doses for control If interstitial radium implant is not indicated, the Co^{60} irradiator often produces sterilization of those masses

The effectiveness and the place of radiation therapy in the management of thyroid cancer has never been definite The advent of supervoltage radiation has not changed the basic policy of treatment, which should be primarily surgical If, however, disease remains in a small area let us say, on the trachea, high-dose radiation to a small volume can be delivered with the Co^{60} irradiator and will possibly aid in control

The early epidermoid carcinoma of the vocal cord can be handled very satisfactorily with 200 kv, although there is some advantage in using Co^{60} because it produces less late skin change In the treatment of the more extensive, extrinsic or intrinsic tumors of the larynx, if a laryngectomy cannot be performed or is refused, Co^{60} teletherapy increases the possibility of cure over that with 200 kv If radiation therapy fails, a laryngectomy can be performed with much less danger of delayed wound healing and necrosis

Thorax—The epidermoid carcinoma of the esophagus and the lung is incurable in the vast majority of cases because when it is first diagnosed the disease is too widespread Two decades of radical surgical approach has taught us a great deal about the mode of spread and causes of incurability Oftentimes surgical resections or radiation treatment are utilized to relieve some specific distressing symptom

The use of rotation technique at 200 kv in the hands of Nielsen in Copenhagen has yielded very satisfactory palliation for cancers of the esophagus in some instances In more than 80% of the cases so treated, the lumen was reopened and swallowing was possible until the time of death Very little more can be expected with supervoltage radiation, and the only advantage of the use of a Co^{60} irradiator is to simplify delivery of the radiation

Whenever operable, bronchogenic carcinomas are best handled by surgery, as the unavoidable lung fibrosis, even with the use of supervoltage radiation, is a distressing symptom It is only in the occasional early case of bronchogenic carcinoma that, due to the location, is unsuitable for surgery that radical radiation therapy is justified In this instance, a simple arrangement of portals can be used with a Co^{60} irradiator, but it must be remembered that, with skillful use of the multiple-portals technique, cures have been obtained in the past with 200 kv No increase in cure rate can be expected from supervoltage radiation Local control of mediastinal nodes producing obstruction of the superior vena cava can be achieved with tumor doses that can be delivered easily at 200 kv, although control can be obtained, perhaps with less systemic discomfort by using Co^{60} therapy Actually grid therapy with 200 kv is probably as good

In those distressing instances of cancer of the thorax, any new therapeutic development always brings about almost mystical hopes An extensive series of cases of both bronchogenic carcinoma and cancer of the esophagus has been treated with supervoltage therapy and always with very disappointing results Supervoltage radiation offers little assistance in the management of these diseases

Female Genital Tract—Stage 1 and early stage 2 cancers of the uterine cervix are best handled by intracavitary radium therapy supplemented with moderate doses of external irradiation to the pelvic walls Until physicians know more of the tolerance for external irradiation of the whole pelvis, the risks of late sequelae should be reserved for late stage 2, stage 3, and stage 4 cancers of the cervix, in which the cure rates are not satisfactory High doses to the whole pelvis are possible with supervoltage therapy and are, therefore, worthwhile in the treatment of cancers that are spread throughout the pelvis Preliminary impressions from several cancer centers seems to indicate that improved cure rates will result from supervoltage therapy in late uterine cancers Advanced tumor of the vagina and all stages of epidermoid carcinoma of the female urethra are also best treated with supervoltage radiation

Conventional techniques of intrauterine and intracavitary radium therapy followed by hysterectomy are still the best way to handle adenocarcinoma of the body of the uterus, and supervoltage radiation is only useful in those cases in which the tumor has spread beyond the confines of the body of the uterus

In selected cases of ovarian tumor, in which surgery has left residual disease within the pelvis, the use of high tumor doses, possibly with supervoltage techniques, may add something to the management of the disease

Urinary Bladder—A tumor of the urinary bladder that is suitable for local treatment, such as electrocoagulation, local radiation, or partial cystectomy, of course, ought still to be handled by these methods When total cystectomy has to be performed, supervoltage radiation should be considered, particularly if there are paravesticular masses Although cure rates may not be greatly improved, one can produce growth arrest with much less discomfort and, therefore, can add to the patient's useful and comfortable life Sufficient numbers of tumors of the urinary bladder have already been treated in various centers to demonstrate that supervoltage therapy is a definite addition in the management of those tumors

Tumors of the Testis and Lymphoma—Both the seminoma and lymphoma can be controlled by doses easily delivered with a 200-kv generator Supervoltage radiation makes the delivery of an adequate tumor dose easier for permanent sterilization of the retroperitoneal nodes or for long-lasting control of retroperitoneal or mediastinal manifestations of lymphoma Embryonal carcinoma of the testis requires tumor doses that are difficult to give with medium voltage, and, although further study will have to be done, there is some possibility that somewhat improved cure rates can be obtained in these tumors by a better control of the retroperitoneal nodes

Miscellaneous Types—There are a number of tumors, usually rare, that show some varying degree of radioresponse, and, if they are located in such areas as the pelvis or the abdomen, the dosage necessary for cure or long-lasting control is more easily delivered with supervoltage radiation For instance, a Ewing s sarcoma of the pelvic bones can be treated best with Co^{60} therapy, because a higher tumor dose can be obtained with the necessary sparing of the skin

At times, radiation for relief of pain due to bony metastases is better achieved with supervoltage radiation due to the utmost necessity of sparing the skin, for instance, the skin above the lower part of the back or the sacrum, so that the possibility of the development of decubitus ulcers when the patient becomes bed-ridden is diminished

In selected cases, a resectable adenocarcinoma of the rectum with recurrences localized to the pelvis can be effectively controlled by supervoltage therapy

The routine postoperative radiation of the internal chain of mammary lymph nodes and supraclavicular nodes after radical mastectomy is still probably best done with a 200-kv generator The depth dose of the supervoltage beam produces fibrosis of the lung and mediastinum that is not justifiable for this adjunctive therapy, which has never been uncontroversially proved to increase the survival rate in breast cancer In the more advanced breast cancer in which surgery alone is no longer effective even in the control of the primary tumor and the regional lymphatics, a combination of preoperative radiation followed by mastectomy or of a simple mastectomy followed by heavy local radiation by the McWhirter method is indicated

Radiation to the whole chest wall, in addition to the lymphatic areas, is imperative and supervoltage helps diminish the severity of the skin reaction.

Summary and Conclusions

The present status of cobalt-60 therapy or supervoltage radiation of the 2-million-volt range can be summarized by the following statements: 1. There is the possibility of increasing tumor doses because of better skin tolerance and a slight increase of the tolerance of the deeper structures. 2. There is no specificity of action on tumor cells and therefore, no fundamental change in the radiosensitivity of tumor cells. 3. The modality of attack always has to be adapted to the natural history of the cancer, as its curability is fundamentally inherent in its biological behavior.

Supervoltage therapy is of no advantage in early accessible cancers treated optimally by low-voltage or medium-voltage x-rays (such as in cancer of the skin and lip) or by intracavitary or interstitial radium therapy (as in early epidermoid carcinoma of the oral cavity and uterine cervix). It does not offer assistance in radioresistant cancers and offers very little in the treatment of widespread cancers even if they are of the radioresponsive type. For instance, in bronchogenic carcinoma supervoltage radiation offers very little more aid than does 200 kv. radiation and probably even no advantage over 200 kv. grid therapy for the relief of symptoms such as mediastinal nodes pressing on the superior vena cava. In those cancers such as cancer of the esophagus no improvement in cure rates can be expected.

It is important to dispel some of the misconceptions concerning supervoltage therapy and Co^{60} teletherapy. These misconceptions are responsible for grave disappointments as well as for the unfortunate physical and financial strain put on patients and their families by their seeking supervoltage therapy in faraway centers.

These misconceptions are (1) that supervoltage has anything to offer in generalized cancers, (2) that the radioresistant cancers are radiosensitive to supervoltage therapy, (3) that treatment of a recurrence after an original radiation treatment is feasible with supervoltage therapy, and (4) that there is any specificity of action on cancers by the various modalities of supervoltage, for instance that Co^{60} teletherapy has something to offer when 2-million-volt x-ray therapy has not.

It should be added that the newer forms of megavoltage equipment now in the process of clinical testing or development will also have no specificity of action. It is possible that, in some instances, there may be a further technical progress but thorough clinical evaluation must be completed before any conclusions can be drawn. It is, however, doubtful that they will represent as great an improvement as the jump from 200 kv. to 2 million volts. Less skin reaction and less loss of radiant energy outside of the beam are the main advantages and only some refinements will be obtained by further technological developments.

The task in the coming decade is more in clinical than physical treatment. Considerable experience is yet to be obtained in the adaptation of supervoltage therapy to those cancers that are still potentially curable in a certain percentage of cases but that have not been curable in the past due to the inability to control the primary disease and the proximal regional metastases. Also closer teamwork between the surgeon and the radiotherapist is in order, because supervoltage radiation broadens the possibility of combined surgery and radiation in many instances.

This clinical testing must be done with objectivity because overenthusiasm and misconceptions are too often conducive to rebounds to underrating the true possibilities. This happened in the 1930s after the first million-volt machines were built and put into clinical use. Primarily the cases treated were hopeless, and as results were very different from those achieved with conventional techniques, it was very hurriedly concluded that supervoltage radiation offered no advantage. It has taken over 15 years for the medical profession to recover from that premature misconception and there is danger of the same thing recurring if an objective and unemotional approach to Co^{60} teletherapy is not preserved.

Limitations of Chemotherapy in Tuberculosis.—With the successful development of potent chemotherapeutic agents in the past several years the effectiveness of chemotherapy in human tuberculosis has not been limited by lack of effective antimicrobial drugs. This has been reflected in the high percentage of cures now possible in tuberculosis. It is perhaps no exaggeration to state that approximately 90 per cent of unselected and previously untreated cases now can be controlled with chemotherapy. This is true not only for pulmonary tuberculosis but similar results have been recorded in tuberculosis of bones and joints, tuberculous meningitis, genito-urinary tuberculosis, laryngeal tuberculosis, etc. It is thus important from a practical clinical point of view to analyze the causes of chemotherapy failure. Moreover, such analysis leads to better utilization of chemotherapy and more effective application of accessory procedures such as surgery or collapse therapy. Sufficient experience has now accumulated to permit tentative efforts at such evaluation. These indicate that limitations of effective antituberculous chemotherapy at the present time stems from three sources: difficulties inherent in the nature of chemotherapeutic agents, those derived fromthe nature of the disease under treatment and, finally, those secondary to biological changes in the bacterial population itself.—I. J. Selikoff, M.D., The Chemotherapy of Tuberculosis, *Journal of the Mount Sinai Hospital*, July-August, 1956.

BLOOD-GROUPING TESTS IN UNDISPUTED PATERNITY PROCEEDINGS

Leon N Sussman, M D
and
Sidney B Schatkin, LL B , New York

• *Persons who were involved in litigation relating to paternity were invited to submit to blood grouping tests after the cases had been settled by the defendant's admission of paternity Cooperation was obtained in 67 cases, and the bloods were typed by the A B O system, the M N system, and the Rh Hr system Three children were found by the A-B O system not to be the offspring of the men who had admitted paternity, similarly the M N and the Rh Hr systems excluded three and two children respectively In one of these instances a child was excluded by both the M N and the Rh Hr systems It was probable that in 12 out of these 67 cases the men who had admitted paternity were not the actual fathers Admissions of paternity were thus found unreliable It is urged, in the interests of justice, that a blood test should be ordered in every case involving a charge of paternity*

Heretofore use of blood-grouping tests, whose value has been firmly established by numerous investigators,[1] has been confined to those cases where the accused man has denied paternity In these contested cases the scientific evidence of the infallibility of an exclusion based on blood tests is such that many states (New York, Maine, New Hampshire, New Jersey, Wisconsin, Ohio, Maryland, South Dakota, North Carolina, Pennsylvania, and Rhode Island[2]) have enacted statutes which make blood test exclusions decisive of the issue However, the majority of men involved in paternity suits do not contest the charge It is this group of cases with which this report is concerned

In the courts where paternity cases are heard, only a minority of the accused men deny paternity This group, therefore, are the only ones who are privileged to request blood tests to sustain their denial It has been shown that 30 to 40% of these men who deny paternity are falsely accused[3] In the majority of cases heard in these courts, however, the accused man admits paternity and accepts the burden of support imposed by the court

Since no direct scientific findings can prove that the defendant is the father, the motivation for an admission of paternity is of interest Usually it is one of these (1) a sincere belief that he is the father, (2) a sense of pride arising from the fact that he could be the father, (3) a total lack of financial responsibility and, therefore, a careless attitude toward the situation, (4) inability to afford defense of the action and costs of blood tests and other evidence, or (5) a state of ignorance which confuses intercourse with paternity

This report presents the findings in 67 cases of uncontested paternity where the involved persons submitted to examination after their suits were completed All of these cases had been settled by the admission of paternity by the defendants, awards for support and expenses had been imposed, and the cases had been closed Subsequent to all court actions, the involved parties then voluntarily submitted to blood-grouping tests Obtaining the cooperation of these persons after their cases were completed was understandably difficult The 67 cases represent the total number in which tests were completed in a three-year period during which over 500 litigants were interviewed and requested to submit to tests The tests were performed in the usual manner of duplicate testing by different technicians using different lots of serum ABO groupings were determined by direct cell typings with known anti-A and anti-B serum, and anti-A + B (O) serum, and by reverse typings with known A cells and B cells with the serum being tested M-N groupings were determined with four anti-M and four anti-N rabbit serums by well and test-tube techniques Rh-Hr groupings were determined by use of saline and "stick" tests with known Rh_0, rh′, rh″, hr′, and hr″ antiserums in duplicate Negative reactions were checked by use of antiglobulin techniques where pure or unblocked serum was used for the testing (Pure′ or unblocked serum refers to a serum containing only a single antibody Thus a pure rh″ antiserum is obtained from a sensitized donor whose phenotype is Rh_1rh, thus lacking only the rh″ factor A blocked Rh_0″ antiserum is not suitable for the antiglobulin test for this purpose, as the test would be falsely positive due to coating of the test cells by the univalent Rh_0 antibody in the blocked serum) Positive and negative controls were incorporated in each run In addition to tests for accepted blood group systems listed in a report[4] on the "Medicolegal Application of Blood Grouping Tests," additional tests were done with anti-Kell serum and anti-P serum

Exclusions Obtained in Sixty-seven Cases of Uncontested Paternity

No	Putative Father	Mother	Children	Excluded by System
1 (Case 2)	O N Rh rh	A MN Rh_2rh	A_2 M Rh_1rh	M N Rh Hr
2 (Case 8)	O MN Rho	O M Rho	(a) O M Rho (b) A_1 M Rho	Not excluded A B O
3 (Case 16)	O MN Rho	B MN Rh_1Rh_1	(a) O N Rh_1Rh_1 (b) O N Rh_1rh (c) B MN Rh_1rh	Rh Hr Not excluded Not excluded
4 (Case 21)	B M Rho	B M Rho	A_1 M rh	A B O
5 (Case 39)	O M Rh rh	O [illegible] Rho	(a) O N Rh_2rh (b) O N Rh rh	M N M N
6 (Case 56)	B N Rh Rho	O M Rho	A_1 MN Rh_1rh	A B O

Attending Physician (Hematology) and Transfusionist, Beth Israel Hospital (Dr Sussman) and Assistant Corporation Counsel of City of New York (Mr Schatkin)

The results obtained, listed in the table, indicate that, of the 67 men involved in these cases of uncontested paternity action, 6 were absolutely excluded as the father of the involved child As has previously been shown, blood groupings using the A-B-O, M-N, and Rh-Hr systems can exclude only 50% of the falsely accused men[1h], it follows that, in fact, 12 or 18% of the accused men who admitted paternity were probably not the fathers of the children they accepted as their own!

Comment

This report again emphasizes the need for use of all the available systems for blood grouping Failure to test with antiserums to determine the subgroups of the Rh system reduces the value of the tests considerably Thus, in this small series of six cases, involving seven children, three children were excluded by the A-B-O system, three by the M-N system, and two by the Rh-Hr system One exclusion involved both the M-N and the Rh-Hr systems Familiarity with these uncommon testing serums and a knowledge of the laws of genetics governing the inheritance of the blood factors are essential to the proper conduct and evaluation of the tests For these reasons the medicolegal aspect of blood testing must be restricted to qualified experts The availability of rapid air transportation makes the expert laboratory easily accessible

In this small series of typical cases of conceded paternity, 18% of the men are probably not the fathers of the children whose paternity they admit This fact has a significant bearing on the reliability of admissions of paternity which are routinely and perfunctorily accepted daily in our courts The courts hould realize that 18% of the men who do not contest he charge are admitting paternity of children not their own In the interests of justice, a blood test should be ordered in every case involving a charge of paternity

Summary and Conclusions

Blood-grouping tests in 67 cases of uncontested paternity indicate that in 6 cases, or 9% the men admitting paternity were not the fathers of the children they accepted Since only 50% of wrongfully accused men can be excluded by present methods of blood testing, it follows that not 6 but actually 12 men in this small series who admitted paternity were probably not the fathers of the children in question The demonstrated unreliability of admissions of paternity should be drawn to the attention of the proper authorities

36 E 38th St (16) (Dr Sussman)

Nongonococcal Urethritis—The effectiveness of the intramuscular form of Terramycin as compared with some other standard forms of treatment in nonspecific urethritis was studied in 57 patients Ninety-five per cent of the patients receiving either sulfadiazine or the oral form of Terramycin were considered cured or improved Terramycin intramuscularly appears to be of some benefit in the treatment of nonspecific urethritis, although inferior to sulfadiazine and Terramycin orally Of those patients receiving no specific therapy, about 65 per cent were considered cured or improved, this points up the difficulty in evaluating any new type of therapy Bacteriologic studies and the nature of the responses to the various antibiotics used lead one to conclude that the hemolytic staphylococcus may play an important role in causing this disease Nonspecific urethritis is a disease that may have a rather prolonged course and that is subject to spontaneous remissions and relapses That it is acquired by sexual intercourse is surmised but by no means proved Because of the apparent frequency of some degree of prostatic involvement "prostatourethritis" rather than 'urethritis" would be a better term for the disease—F S Wolf, M J Thoshinsky, Sanford Chodosh, and J O Arrington Jr, Therapy of Nongonococcal Urethritis, *United States Armed Forces Medical Journal*, June, 1956

INTESTINOVESICAL FISTULAS

REPORT OF SEVEN CASES AND REVIEW OF THE LITERATURE

Benjamin S. Abeshouse, M.D., Martin A. Robbins, M.D., Mark Gann, M.D.
and
Julian O. Salik, M.D., Baltimore

• *Whether the cause of intestinovesical fistula is inflammatory, neoplastic, or traumatic, the mechanism of production is localized intestinal pathology, abscess formation, and extension to the bladder. The diagnosis is made from a history of passing gas and feces from the urinary tract. The best treatment is a multistage procedure, with the colostomy first, and then resection of the intestine and fistulous area of the bladder; cystostomy is not always necessary.*

Although relatively few articles have been written on the subject of intestinovesical fistula in the past 15 years, the literature prior to 1940 is replete with numerous reports. Our recent experience with the condition prompted this report of seven cases with a review of the literature and reevaluation of the subject from the standpoint of diagnosis and treatment.

Since ancient times, the passage of feces and air via the urethra has been considered pathognomonic of intestinovesical fistula. In 1888, Cripps wrote a classic study entitled "Passage of Air and Fæces from the Urethra."[1] Many of the fundamental facts and views elucidated by him are still valid today. He emphasized that in most cases, whether neoplastic or inflammatory in origin, secondary abscess formation rather than direct extension of the lesion was the chief factor in the production of fistulas. Those interested in the historical background of the subject are referred to the excellent review articles by Morrissey, Kellogg,[1A] Higgins,[2] and Parham and Hume.[3]

Etiology

A simple classification of intestinovesical fistulas based on the etiology has been employed by many authors and divides these fistulas into five main types: (1) congenital, (2) traumatic, (3) inflammatory, (4) neoplastic, and (5) foreign body. A comparison of the relative frequency of the etiological factors is summarized in the table.

In recent years, there has been a noticeable change in the nature of the primary causative factors of this disease. This is borne out by the experiences at the Mayo Clinic. In 1921, Sutton,[4] of the Mayo Clinic, reported on 34 surgically treated cases, of which 38.23% were secondary to infection in the fallopian tubes and only 17.6% due to diverticulitis. Subsequently in 1950 Mayo and Blunt[5] collected 202 proved cases of diverticulitis seen at the Mayo Clinic between 1939 and 1948 and observed intestinovesical fistulas in 46, or 22.8%, of the patients.

There is little mention in the literature in regard to regional ileitis (Crohn's disease) as an etiological factor. Recently, Black and Bolt[6] and Williams[7] have reported single cases. Williams[7] collected 365 cases of regional ileitis, with 23 ileovesical fistulas. Robinson[8] reports three cases of ileitis with vesical fistula. According to Williams,[7] congenital fistulas are practically always associated with imperforate anus. Ladd and Gross reported 214 cases of imperforate anus and observed fistulas between the rectum and bladder in 117 of them.

Traumatic fistulas are produced either by external violence (chiefly gunshot wounds) or by surgical injury. The latter type may occur after instrumentation, i.e., passage of a metallic sound, cystoscope, or resectoscope, or during surgery. Williams[7] noted 22 traumatic cases in a series of 148 intestinovesical fistulas. Ten of the 22 cases occurred after prostatectomy; most of them were rectourethral or at the bladder neck. In all probability, traumatic fistula is more commonly encountered than reports would indicate. We have seen three cases of intestinovesical fistula resulting from operative trauma, i.e., after suprapubic prostatectomy, resection of posterior bladder for neoplasm, and operation for imperforate anus. These cases have not been included in this report.

Inflammatory conditions represent the most common cause of fistulas. Not infrequently the primary causative lesion in cases of inflammatory fistula is an unsuspected carcinoma of the intestine or other adjacent organs whose presence is revealed at operation or autopsy. In the majority of instances of intestinovesical fistula, regardless of the cause, there is abscess formation and extension to and communication with the bladder. The chief primary inflammatory disease encountered is diverticulitis of the sigmoid. Regional enteritis is next in frequency. Rarely, fistulas may form as a result of appendicitis or cecal or pelvic inflammatory disease.

Neoplastic disease ranks a close second to inflammatory disease as a causative agent. Carcinoma of the rectosigmoid is the most common lesion. In the series of 34 cases collected by Higgins[2] at the Cleveland Clinic, 13 were due to carcinoma of the lower part of the intestine, i.e., 7 sigmoid, 2 rectosigmoid, and 4 rectal. Neoplasms of the bladder or female pelvic organs are rarely primary causative factors.

There have been scattered reports of the production of intestinovesical fistulas as a result of ingestion of foreign bodies. Herbst and Miller[9] reviewed the literature and reported a case that occurred after the patient had swallowed a chicken bone. The chief offenders have been bones and pins swallowed acci-

Read before the Section on Urology at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956.

dentally In a few instances, there was some doubt as to whether the foreign body was ingested or inserted via the urethra In most cases the foreign body becomes lodged in the lower part of the intestine and initiates an inflammation with perforation, abscess formation, and fistula

Appendicovesical fistula represents a rare type of fistula Pemberton and co-workers [10] reported only five cases from the Mayo Clinic In three of these cases there was an antecedent history of acute appendicitis Goldstein [11] reported a case in which a biopsy was performed and fulguration done on a tumor on the right lateral wall of the bladder The tumor subsequently proved to be the appendix protruding into the bladder

It is of interest to note that intestinovesical fistula occurs more frequently in males than females (3 2) The interposition of the uterus between the intestine and the bladder apparently serves as a defensive barrier against the spread of infection from the sigmoid colon to the bladder in the female

Relative Incidence of Different Types of Intestinovesical Fistulas as Found by Various Authors

Williams	6	22	64	51
Total	30(5%)	109(15%)	216(33%)	310(47%)

Pathogenesis and Symptoms

The mechanism of production of an intestinovesical fistula is essentially the same whether the cause is inflammatory, neoplastic, or traumatic The primary requisite is localized intestinal pathology with perforation, abscess formation, and extension to the bladder The lower part of the intestine, with its many virulent organisms, is often the chief site because of its proximity to the bladder The two most common conditions in the rectosigmoid, i e, diverticulitis and carcinoma, are the frequent causative agents

There are two pathways by which the infection spreads to the bladder 1 Adherence to the bladder via an abscess In this manner, as in diverticulitis, a marked peridiverticulitis develops with abscess formation and adherence to the bladder and subsequent rupture into the bladder This mechanism is commonly described in the literature 2 Extension of an inflammatory or suppurative process from the diverticulum along the mesosigmoid and/or the ureter to the base of the bladder and thence into the bladder This mechanism was encountered in four of our seven cases of fistula We have found only scant reference to this in the literature Since the most common site of intestinovesical fistula is in the region of the trigone of the bladder and ureteral orifice, which are retroperitoneal structures, it is our belief that the latter is a more common pathway of spread than has been appreciated up to this time

In most instances, it is difficult, in either the fresh or the fixed specimens, to identify the fistulous tract Usually, the tract is so tortuous that it defies dissection, and one sees only a mass of chronic inflammatory tissue Mayfield and Waugh [12] made a careful pathological examination of specimens in 32 cases of sigmoidovesical fistulas, and in only one case was the fistulous tract definable

In the fully developed case of intestinovesical fistula, the diagnosis can be made from the history The usual story is one of passing gas and feces via the urinary tract, with concomittant urgency, frequency, and dysuria due to the associated cystitis There may be hematuria in the later stages Symptoms and signs of the primary causative disease may also be present In most cases, there is pain in the lower part of the abdomen and constipation The fistulas in the lower part of the colon usually do not lead to passage of urine into the colon The higher the site of the intestinal communication, the more likely it is for urine to appear in the stool In ileovesical fistulas, the patient will frequently pass urine per rectum

Many authors have emphasized a stage in the development of the disease prior to the actual fistula formation In this prodromal stage, in which there is abscess formation and pericystitis, the only symptoms indicating the disease may be those referrable to the bladder Lazarus and Marks [13] emphasized an incipient stage before fistula formation, when the threatened breakthrough is manifested by the sudden onset of frequency, urgency, burning, pyuria, and albuminuria When the breakthrough occurs, it may be explosive in onset, with severe tenesmus and strangury due to the acute cystitis This may then pass into a chronic stage Some patients may have pneumaturia and fecaluria for several years before they seek help Mayo and Blunt [5] noted an average duration of symptoms of 18 5 months in 48 patients with vesicosigmoid fistula before they sought medical care

The diagnosis is suggested by the clinical history and physical signs Cystoscopy may be of value in establishing the diagnosis During the incipient stage, one may observe a localized area of cystitis with edema and engorgement of the vessels, generally on the left side near the base of the bladder After fistula formation, there is edema, marked cystitis, and particulate fecal matter in the urine One rarely observes the actual fistulous opening because of the associated inflammatory changes and bullous edema

Proctosigmoidoscopy has virtually little diagnostic value The fistula may be demonstrated by either a cystogram or a barium enema When in doubt, one may instill methylene blue or sodium indigotindisulfonate (indigo carmine) in the bladder and recover it in the stool One may also feed the patient charcoal by mouth and recover the substance in the urine

Treatment

No single mode of treatment is applicable to all cases The method depends upon such things as the general condition of the patient, the nature of the disease in the intestine, the status of the urinary tract, and the duration of the condition In general it is agreed that a multistaged procedure is best

Mayo and Blunt[5] recommended preliminary colostomy in cases of vesicosigmoidal fistula In two patients in whom the fistula was divided and the opening in the sigmoid and bladder closed, there was a recurrence of previous signs and symptoms In 46 patients treated by a preliminary colostomy the mortality was lowest (6 5%) Balch reported 19 cases of vesicosigmoidal fistula and noted that the patients in whom attempts were made to close the fistula before colostomy was performed did poorly Rankin and Brown[14] stated that 'any attempts to locally excise the fistula without bowel resection is doomed to failure' and stressed the value of preliminary colostomy This stand is also advocated by Kellogg[1A] and by Sutton[4]

It is now the accepted practice to perform the colostomy first and then resect the intestine and fistulous area of the bladder It is not always necessary to perform a cystostomy The bladder can be closed primarily and drained per urethra

The length of time elapsing between colostomy and resection depends upon the general improvement of the patient Occasionally, the fistula may close spontaneously after the fecal stream is diverted, but this does not preclude further section In the poor-risk patient or in the patient with inoperable carcinoma a permanent colostomy may be adequate palliation In one of our reported cases (case 5), the elderly patient refused further surgery after the colostomy and was content to live in that manner

Mayo and Miller[15] reviewed 88 cases of sigmoidovesical fistula treated surgically at the Mayo Clinic and reported that 35 patients were cured, 5 improved, 4 unimproved, and 4 had recurrence There were 26 deaths related to the primary disease or operation The above statistics substantiate the fact that this condition is a serious disease and requires diligent and long term care

Report of Cases

CASE 1 —A 55-year-old woman was admitted to the hospital on March 31, 1949, with a *complaint of chills and fever and* nausea and vomiting for the previous three months In addition, there was marked shortness of breath and orthopnea The patient was treated at home with penicillin, but the fever recurred The patient also complained of low back pain and pain in the bladder region after voiding She stated that she had seen gas bubbles in her urine since October, 1948 She had a history of rheumatic heart disease with congenital septal defect

Physical examination revealed an acutely ill, malnourished female The temperature was 103 F (39 4 C) The blood pressure was 115/70 mm Hg The patient was dyspneic and orthopneic There were rales at both bases and a *systolic* murmur in the pulmonic area Abdominal examination revealed a tender mass in the suprapubic area *On* pelvic examination there was a rectovaginal fistula There was also generalized immobility of the pelvic structures suggesting a pelvic abscess or neoplasm There were gas bubbles in the catheterized bladder urine The urine appeared grossly cloudy and had a fecal odor Microscopic examination revealed numerous pus cells, and there was 1+ albumin The urine culture revealed Escherichia coli and Proteus vulgaris A barium enema revealed diverticulosis and diverticulitis of the sigmoid colon Cystoscopy was not performed She was placed on a regimen of streptomycin and daily creosol douches A preoperative diagnosis of diverticulitis of the sigmoid with abscess formation was made

On April 7, 1949 a pelvic puncture was attempted through Douglas pouch and the anterior bladder wall, but the mass was noted to be firm On April 11, 1949, an exploratory laparotomy was performed and a large mass involving the sigmoid and bladder was noted in the pelvis A transverse colostomy was performed The patient was discharged on April 24, 1949

She was readmitted on June 5, 1949, and on June 9, 1949 a rectosigmoid resection and telescoping anatomosis were performed Pathological examination revealed diverticulitis with peridiverticulitis and abscess formation involving the bladder Postoperatively, she was placed on therapy with bishydroxycoumarin (Dicumarol) She developed a purulent drainage from the lower angle of the wound, and a large abscess was opened Methylene blue was put into the distal loop of the colostomy and came through the drainage area The drainage gradually diminished On July 5, 1949, the colostomy was closed On July 8, 1949, the patient died suddenly, and the presumptive diagnosis was pulmonary embolus An autopsy was not performed

CASE 2 —A 59-year-old man was admitted to the hospital on Oct 31, 1947, with the complaint of hematuria The patient had noted bloody urine for the first time two weeks prior to admission One year before that, a bladder tumor (papilloma) had been resected transurethrally at another hospital He stated that he had had frequency, urgency and nocturia for five years

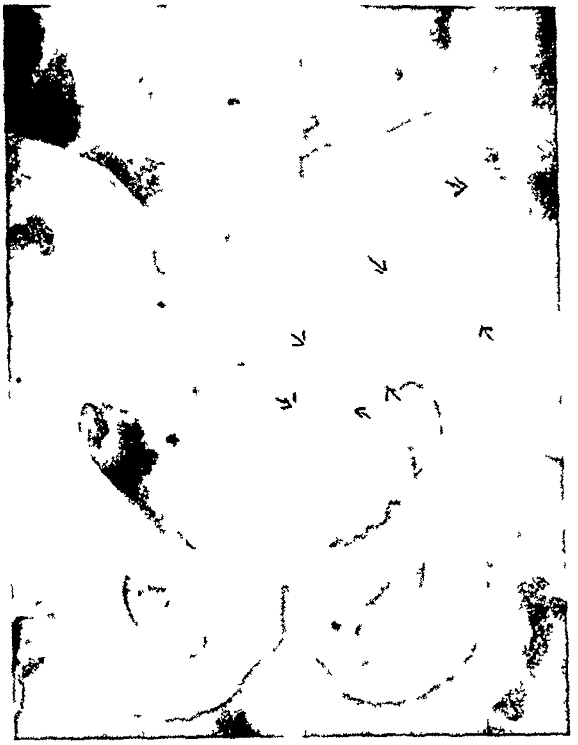

Fig 1 (case 2) —Cystogram showing dye (3 5% sodium iodide) passing from bladder into rectosigmoid

The history and system review were essentially negative except for chronic constipation for the past 12 years for which he had taken laxatives regularly

Physical examination revealed a well-developed well nourished, elderly male not acutely ill The temperature was 99 8 F (37 7 C), and the blood pressure was 108/80 mm Hg Heart and lungs were normal The bladder was distended to the umbilicus Examination of the genitals revealed a dark bloody discharge from the penis At the base of the penis was a red tender area The presumptive diagnosis was (1) recurrent bladder tumor, (2) abscess of the penis, (3) benign prostatic hypertrophy, grade 1, and (4) right inguinal hernia The urine contained 15 white blood cells per high-power field

On admission to the hospital, the patient was catheterized and two emesis basins full of bloody urine with new and old clots were obtained Cystoscopy was performed shortly afterward, and a small vesical calculus with diffuse cystitis was noted Retrograde pyelography disclosed normal kidneys The abscess in the penis was incised and drained Thereafter, the patient continued to show pus in the urine Urine culture revealed Esch coli The patient also ran a spiking fever and on the third day after cystoscopy he began to drain fecal matter per catheter A cystogram was performed, and the dye passed from the bladder into the sigmoid (fig 1) Cystoscopy was repeated, and the findings were unchanged No definite fistulous opening was seen Findings from a gastrointestinal series and a barium enema were negative

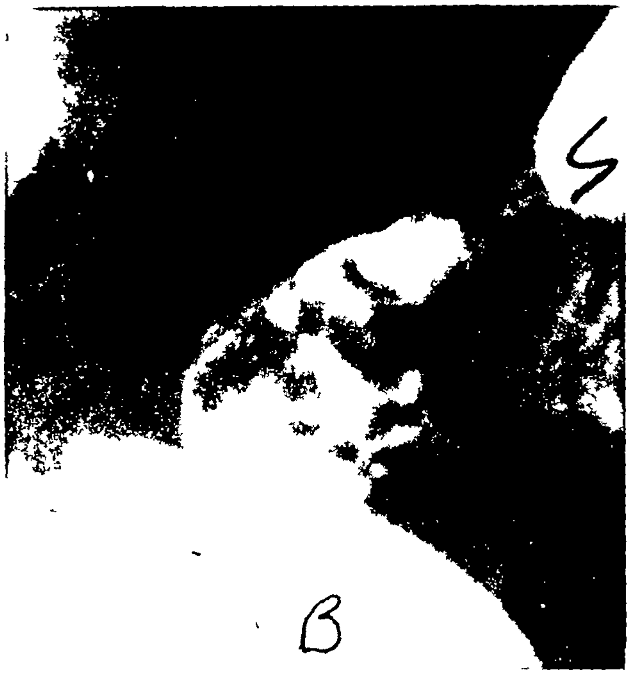

Fig 2 (case 3) —Barium enema showing fistulous tract (F) extending from sigmoid (S) down to bladder (B)

The patient was prepared for operation by the use of a Miller-Abbott tube and the administration of phthalylsulfathiazole (Sulfathalidine) At operation, the sigmoid was found adherent to the bladder and markedly inflamed The involved portion of the sigmoid and bladder were removed in toto, and end-to-end anastomosis was performed on the sigmoid A suprapubic cystostomy was also performed The pathology report indicated a diverticulitis of the colon with perforation, abscess formation and vesicosigmoid fistula The patient made an uneventful recovery and was discharged as cured

Case 3 —A 52-year-old woman was first admitted to the hospital on Oct 23, 1950 with the complaint of pain in the left lower quadrant of the abdomen of two weeks duration She had also noticed pain in the left costovertebral angle with radiation into the left groin At times the pain was quite sharp and colicky in nature During this time the patient had occasional nausea and vomiting There was no change in bowel habits She also had epigastric pain and anorexia There was weakness and generalized malaise She had had vaginal bleeding on two occasions in the past five years A gynecologic operation, whose exact nature could not be determined had been performed two years before at another hospital She had had an appendectomy 30 years before The patient had noticed moderate frequency of urination, slight burning on urination and nocturia (she urinated three or four times nightly) for several years

Physical examination disclosed the patient to be well developed, well nourished, and chronically ill The heart and lungs were normal Blood pressure was 96/70 mm Hg Examination of the abdomen revealed tenderness in the left costovertebral angle and along the left side of the abdomen There was also tenderness in the midline above the symphysis There was also an irregular mass palpable in the left lower quadrant Urinalysis was negative The serum urea level was 31 mg per 100 cc The hematocrit reading was 41% The white blood cell count was 9 750 per cubic millimeter, with a normal differential count Cystoscopy revealed a filling defect caused by pressure on the posterior wall of the bladder from without There was no evidence of ulceration or fistula formation in the bladder The findings on bilateral retrograde pyelograms were negative A barium enema revealed diverticulitis and inflammatory abscess extending into the bladder with possible intrinsic polyps in the rectum (fig 2)

An exploratory laparotomy was performed, and a mass th size of an orange was found lying on the anterior surface of th uterus The mass involved the sigmoid and bladder and lef adnexa, and a presumptive diagnosis of diverticulitis with abscess formation and incipient intestinovesical fistula was made A colostomy was performed The patient made an uneventfu recovery

She was readmitted on Dec 31, 1950, and a resection of th sigmoid colon and left adnexa was performed The mass wa freed from the bladder by blunt and sharp dissection and di not perforate through the wall of the bladder Examination o the excised specimen revealed marked diverticulitis and peridiverticulitis with abscess formation of the sigmoid colon Th patient made an uneventful recovery She was readmitted o Feb 8, 1951, at that time closure of the colostomy was performed The patient was discharged as cured

Case 4 —A 49-year-old man was admitted to the hospital o June 5, 1953, with the chief complaint of pain in the lowe part of the abdomen Four days prior to admission the patien had noted the sudden onset of pain in the left lower quadra of the abdomen with a feeling of pressure over the bladder an urgent desire to urinate There was no incontinence, hematuria or pyuria The pain continued until the day prior to admission At that time the pain in the left lower quadrant of the abdomen became quite severe and colicky and was accompanied by nausea and vomiting There was no diarrhea or blood in the stool

Physical examination revealed a well developed, well nourished, middle-aged male who appeared to be very uncomfortable because of pain in the abdomen The blood pressure was 142/90 mm Hg, the pulse rate was 100 and the respiration rate 16 per minute Examination of the abdomen revealed tenderness in the left lower quadrant with rebound There was no mass palpable Rectal examination was negative The genitals were normal The bladder did not appear to be distended Cystoscopy was not performed, but cystography revealed a filling defect on the superior aspect of the bladder with displacement of the entire bladder to the left Excretory urography was negative The urine showed 5 to 10 white blood cells per high power

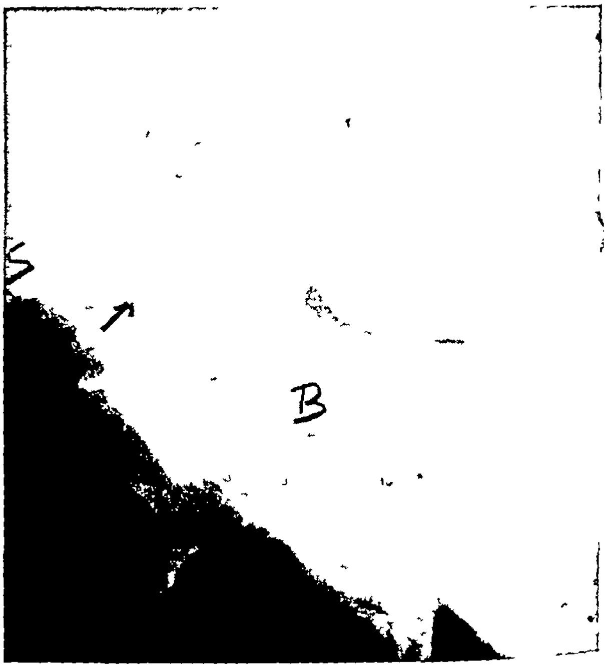

Fig 3 (case 4) —Barium enema (lateral oblique film) showing fistulous tract (F) between sigmoid (S) and bladder (B) field, with 1+ albumin A barium enema was performed and revealed diverticulitis and diverticulosis of the sigmoid colon with a fistulous tract extending into the bladder (fig 3)

On June 8, 1953, an exploratory laparotomy was performed, and in the midportion of the sigmoid there was an abscess surrounding an area of presumed ruptured diverticulum extending down toward the bladder and firmly adherent to the bladder There was marked induration of the mesentery A transverse colostomy was performed On June 10, 1953, the patient passed gas through the urethra Methylene blue was instilled in the distal loop of the colostomy and appeared in the urine This established diagnosis of intestinovesical fistula The postoperative course was stormy, with high fever The patient was given chlortetracycline (Aureomycin) hydrochloride and neomycin sulfate, and his fever subsided He was discharged on June 25, 1953

On Sept 23, 1953 the patient was readmitted for operation, which disclosed that the sigmoid colon was involved in an inflammatory mass The sigmoid was resected and an end-to end anastomosis performed The patient made an uneventful recovery and was discharged on Oct 1, 1953 He was readmitted to the hospital on Dec 27, 1953 for closure of the colostomy This was done without incident, and the patient was discharged on Jan 6, 1954, as cured

Case 5 —A 70 year-old man was admitted to the hospital on Aug 3, 1953 with the chief complaint of anorexia, lethargy, and weight loss for the past five months He had also noted intermittent diarrhea which at times became debilitating For several days prior to hospital admission he had had severe pain in the left lower quadrant and progressive difficulty in voiding His stools had been very watery for a few days prior to admission There were no bloody or tarry stools No hematuria was observed Language difficulty made it almost impossible to obtain an accurate history from this patient

Physical examination revealed him to be an elderly male who appeared acutely ill, dehydrated, and in a toxic condition The blood pressure was 80/60 mm Hg, the temperature was 101 2 F (38 4 C), and the pulse rate was 96 Examination of the abdomen revealed marked distention with rebound tenderness in the left lower quadrant There was no mass Borborygmi were heard The genitals were normal Rectal examination revealed a 2+ benign enlargement of the prostate On the anterior wall of the rectum there was a firm, irregular shelf-like mass, which was not tender The patient was catheterized, and an indwelling Foley catheter was inserted About 300 cc of foul-smelling urine, with a fecal odor, was obtained Proctoscopic examination to a distance of 17 cm was negative for pathology The barium enema was performed, and on fluoroscopic and radiographic examination it was disclosed that there was a narrowing in the region of the sigmoid The barium seemed to escape through a fistulous tract into the bladder (fig 4) Several diverticula were present in the sigmoid

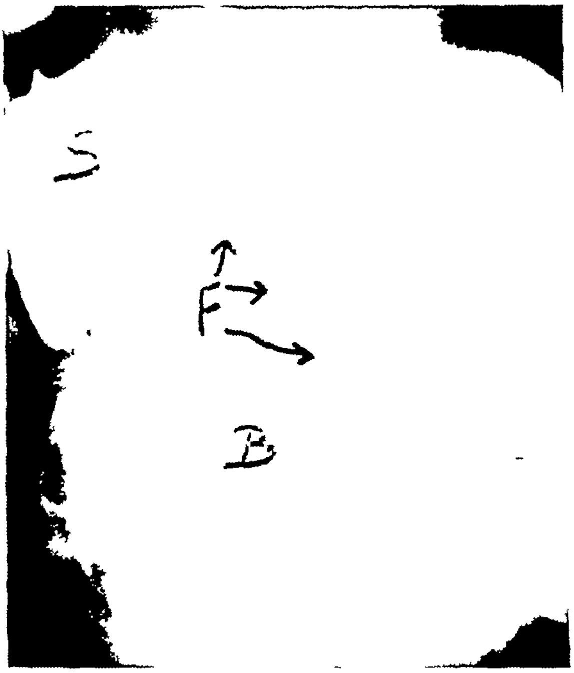

Fig 4 (case 5) —Barium enema (lateral oblique film) showing fistulous tract (F) between sigmoid (S) and bladder (B)

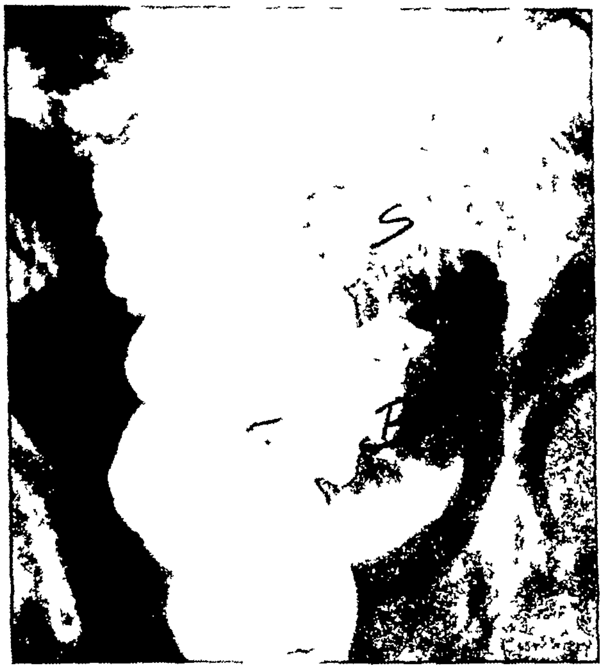

Fig 5 (case 6) —Barium enema (lateral oblique film) showing fistulous tract (F) between sigmoid (S) and bladder (B)

Excretory urography was performed and revealed prompt bilateral excretion, but the outline of the upper urinary tracts was poor in detail Urinalysis revealed urine with a fecal odor with 4+ albumin The urine contained innumerable red blood cells, white blood cells, and casts Culture of the urine revealed Esch coli

On Aug 6, 1953, operation disclosed a firm, lemon sized mass in the region of the sigmoid above the peritoneal reflection There was free fluid in the abdomen The large intestine proximal to the lesion was dilated, edematous and reddened There was a firm mass adherent to the posterior wall of the bladder A transverse colostomy was performed The patient had a prolonged convalescence with fever and protracted anemia He developed a leukopenia and neutropenia and was given multiple blood transfusions Uremia and pneumonitis ensued but cleared with intensive treatment

On Aug 21, 1953, cystoscopy was performed and enlarged prostatic lateral lobes were observed There was bullous edema and tumefaction in the right midline on the posterior lateral wall On Sept 4, 1953, the barium enema was repeated and the retrograde flow of barium failed to show the fistula On Sept 21, 1953, cystoscopy was repeated and essentially the same findings noted On Sept 23, 1953 excretory urography was performed and the left genitourinary tract failed to visualize On Oct 14, 1953, a barium enema was performed that showed diverticulitis and diverticulosis of the sigmoid and a perforated diverticulum producing a fistulous tract leading to the bladder The patient's condition improved, and further surgery was advised but refused He was discharged with the colostomy functioning He failed to return for further observation

Case 6 —A 51-year-old man was first admitted to the hospital on April 27, 1954, with the complaint of having passed dark brown urine for three months The urine had an odor of stool One month prior to admission, he had begun to notice that he had frequency and nocturia and intermittent low back pain The review of the other systems was negative

Physical examination revealed a well developed, well-nourished middle-aged male not acutely ill The blood pressure was 130/80 mm Hg There was a questionable mass in the left lower quadrant in the region of the large intestine, which was tender The genital organs were normal Rectal examination was essentially negative Excretory urography revealed normal pelves, calyces and ureters on both sides There was a pressure defect on the fundus of the bladder that appeared to be due to an extrinsic mass On April 28, 1954 cystoscopy revealed the bladder to be inflamed, and on the left side there was a mass extending from the vesical neck onto the posterior wall with marked bullous edema No definite fistulous tract could be seen A barium enema was performed and revealed a fistulous tract between the terminal ileum and the sigmoid and between the sigmoid and bladder (fig 5) and diverticulitis of the sigmoid and distal third of the descending colon

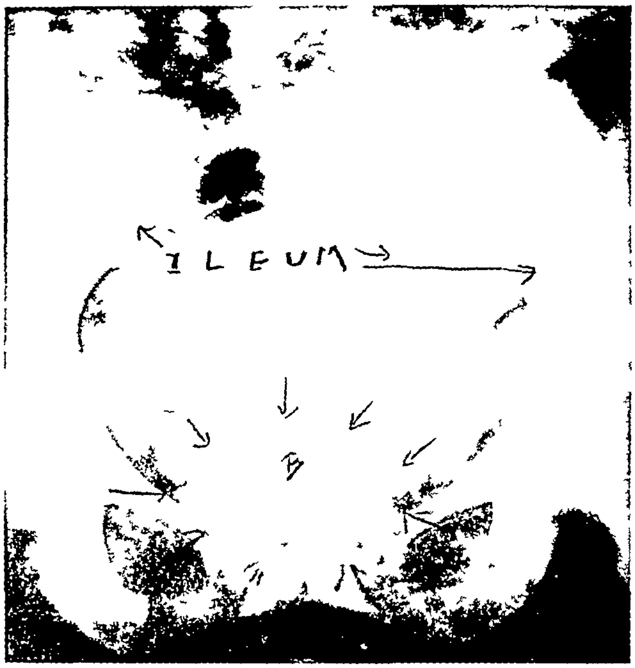

Fig 6 (case 7)—Cystogram showing dye (3 5% sodium iodide) passing from bladder (B) into ileum (I)

On May 11, 1954 a transverse colostomy was performed, and during operation a large inflammatory mass was found incorporating the sigmoid colon bladder and small intestine On Aug 11 1955, the patient was readmitted to the hospital At operation, the sigmoid was removed after the small intestine was freed up and a sigmoidosigmoidostomy and a suprapubic cystostomy were performed The small intestine and omentum were markedly adherent to the mass When the sigmoid colon was opened in the excised specimen a probe could be passed through a fistulous tract into a portion of the excised bladder The patient had an uneventful postoperative course On Sept 27 1955, the patient was readmitted to the hospital for closure of the colostomy and had an uneventful course thereafter

Case 7—A 54-year-old woman was first admitted to the hospital on Feb 3, 1955 She gave a history of having had a carcinoma of the cervix for which she had received radium therapy and deep x-ray therapy in 1938 She had developed a stricture of the right ureter and had been receiving periodic ureteral dilatations In 1953, there was no evidence of recurrence of the carcinoma On Sept 1, 1954, a right nephroureterectomy was performed for a massive hydropyoureter and for hydronephrosis At that time the patient had suffered from recurrent chills and fever

The patient stated that she had been passing urine per rectum for three weeks prior to her last hospital admission She had also passed scant amounts of urine through the urethra with great difficulty She had not urinated through the urethra for several days prior to her hospital admission

Physical examination revealed a fairly well developed, well nourished female, not acutely ill The blood pressure was 170/90 mm Hg, the pulse rate was 108, the temperature was 98 6 F (37 C) Examination of the abdomen revealed generalized tenderness with no masses The blood urea level was 104 mg per 100 cc The hematocrit reading was 35% The urine showed many red blood cells and a few white blood cells, with clumps and 2+ albumin Cystoscopy was unsatisfactory because of marked inflammation Excretory urography revealed the left ureter to be dilated Cystography revealed a communication between the bladder and ileum (vesicoileal fistula) (fig 6) Findings from the barium enema were negative A cystogram revealed the bladder to be trabeculated, and the dye passed readily into the ileum A small intestinal series showed the barium passing from the small intestine into the bladder (fig 7) and remaining there for more than six hours An electrocardiogram was compatible with coronary insufficiency Proctosigmoidoscopy was negative

On Feb 11, 1955, an exploratory laparotomy was performed and revealed the ileum to be adherent to the bladder The intestine was resected, exteriorized and drained, and the small intestine was reunited end to end The patient was discharged on Feb 26, 1955 She was readmitted on March 15 1955, with the complaint of generalized abdominal pain and the passing of stool in the urine A cystogram revealed a sigmoidovesical fistula at this point Excretory urography showed a marked hydronephrosis on the left with a hydroureter Abdominal operation was performed, and the intestine and a portion of the bladder to which it was attached were excised A transverse colostomy and a ureterocutaneous anastomosis on the left were performed

The patient had a very stormy postoperative course and went rapidly downhill She died with fever and septicemia on April 27, 1955 Autopsy revealed recurrent carcinoma of the cervix with extension into the uterus and bladder and a vesicosigmoid fistula There was metastasis to the liver, mesenteric lymph nodes, and intestinal tract There was generalized pelvic peritonitis

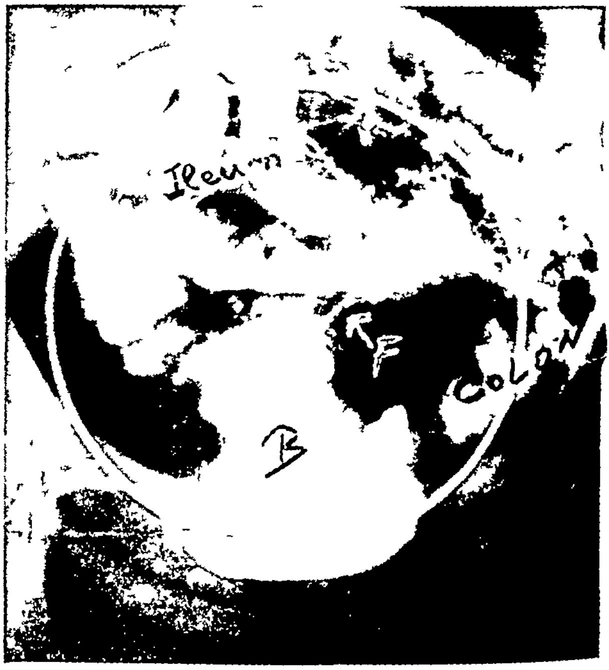

Fig 7 (case 7)—Barium enema showing fistulous tract (F) between ileum and bladder (B)

Summary and Conclusions

Five of seven patients with intestinovesical fistula were in the sixth decade of life, the youngest was 49 years of age and the oldest 70 years Four were males and three females The etiological condition responsi ble for the intestinovesical fistula was, in six cases diverticulitis with abscess formation extending downward and into the bladder in the remaining case the fistula was secondary to a carcinoma of the cervix A olitary fistula was present between the sigmoid and he bladder in the five cases due to diverticulitis and accompanying abscess formation In four of these cases the abscess opening was located in the posterior wall of the bladder in or adjacent to the trigone In one case (case 3) true fistula formation was not demonstrated in the bladder as the abscess from the diverticulitis extended down to but not through the bladder wall thus the diagnosis is a presumptive one and the condition may be regarded as being diagnosed in the prefistulous or incipient stage One patient (case 6) also had a fistula between the sigmoid and ileum

A correct preoperative diagnosis was established in five cases (cases 1 2 5 6 and 7), in each of which fecal particles were seen in the urine The fistulous communication between the bladder and sigmoid was demonstrated by cystography i e passage of dye from the bladder into the intestine in two cases (cases and 7) and by passage of barium from the intestine into the bladder in four cases (cases 3 4 5 and 6)

Operative treatment was carried out in each case with only two mortalities the patient in case 1 died of pulmonary embolus on the third postoperative day after closure of colostomy and the one in case 7 died of septicemia after a lengthy operation consisting of a combined excision of the vesicosigmoidal fistulous tract, transverse colostomy and a ureterocutaneous anastomosis on the left One patient (age 70) obtained a good result after a transverse colostomy and refused further surgery In other cases, with the exception of case 2, multistaged operative treatment was employed consisting of (1) colostomy (2) excision of fistulous tract and resection of intestine, and (3) closure of colostomy In case 2 a one stage operation consisting of excision of fistulous tract end to end anastomosis of intestine, and suprapubic cystostomy was successfully performed A suprapubic cystostomy was employed in only one other case (case 6)

A review of the literature and personal experience with seven cases warrant the following conclusions Intestinovesical fistula is a serious condition presenting difficult problems in diagnosis and requiring a carefully planned multistaged operative treatment The condition can be classified according to the most common etiological factors in order of frequency as follows (1) inflammatory (2) neoplastic, (3) traumatic, (4) congenital and (5) foreign body In the majority of cases of intestinovesical fistula there is an associated abscess formation with extension to and communication with the bladder The diagnosis of intestinovesical fistula is suggested by the clinical history, that is, passage of gas and feces in the urine with concomitant urgency, frequency, and dysuria and the physical signs, that is, pain, tenderness, and a mass in the left lower quadrant

Cystoscopy may be of value in establishing the diagnosis In the fully developed case, edema, marked cystitis, and particulate fecal matter in the urine are usually observed but the fistulous opening is not visualized due to the bullous edema and inflammatory changes In the incipient stage, localized inflammation and edematous changes and inward bulging of the posterior bladder wall at or near the trigonal area are noted The fistulous opening may be demonstrated not infrequently by either a cystogram or barium enema Occasionally, instillation of methylene blue or sodium indigotindisulfonate (indigo carmine) into the bladder may lead to recovery of the dye in the stool Surgical treatment varies with the duration and severity of the pathological process In most instances the best results have been obtained by employing a multistaged operative plan, namely, (1) colostomy, (2) combined excision of fistulous tract and intestinal resection, and (3) closure of colostomy

The early diagnosis of diverticulitis with or without abscess formation and the institution of prompt surgical treatment will prevent the development of intestinovesical fistula Close cooperation between the gastrointestinal specialist or internist, the surgeon, the urologist, and the radiologist will insure early diagnosis and appropriate surgical treatment

BETA-PROPIOLACTONE IN STERILIZATION OF VACCINES, TISSUE GRAFTS, AND PLASMA

Frank W Hartman, M D
and
Gerald A LoGrippo, M D, Detroit

• *Beta propiolactone seems to be a superior sterilizing agent for biologicals because of its capacity to inactivate a wide variety of bacteria, fungi, and viruses At the same time, this chemical has a minimal effect on proteins, avoiding final neutralization, and produces relatively nontoxic end products The rapid penetration of tissues allows safer and more homogenous tissue grafts of arteries, bone, and cartilage Although use of the product against the hepatitis viruses has not been studied, since this is yet not possible, beta-propiolactone produces plasma that will keep for long periods and will be well tolerated by patients*

The usual process of sterilization by physical or chemical methods results in radical changes in the medium or environment containing the micro-organism concerned The sterilization of biologicals, such as vaccines, tissue grafts, and plasma, involves as the first consideration, beyond that of the lethal effect on the micro-organisms, the preservation of the proteins in or near their original state In the case of vaccines, preservation of the bacterial or virus proteins in their original state should be attained as far as possible so that the resulting antigen will produce antibodies comparable to those obtained using the same organisms in the viable state In the case of plasma, denaturization of the proteins is to be avoided so that they will remain nontoxic and nonantigenic and will retain their normal in vivo functions and survival In the case of tissue grafts, it is essential to obtain nontoxic, nonantigenic material that will function without producing complications when transferred to the patient

The efficiency of heat, the most efficient and widely used physical bactericidal agent, is paralleled by the coagulation of proteins The same is true of the two bactericidal chemical agents, phenol and formalin, which are most commonly used in biological applications These chemical agents have the further disadvantage of remaining intact in the end-product and, hence, may be toxic when used in plasma, tissue grafts, or vaccines

It is well established that a number of virus infections in man are accompanied by a phase of viremia Some of these, such as serum and infectious hepatitis, produce a carrier state resulting in clinical cases of hepatitis in the recipient of such a carrier's blood With the constantly increasing utilization of blood, blood plasma, homologous tissue grafts, and vaccines, it becomes imperative to develop methods of sterilization that will insure the maximum safety and effectiveness of these various products

Over the last five years more than 500 chemical compounds have been screened,[1] with special emphasis on the finding of one that would inactivate the virus of serum hepatitis in blood and blood plasma Beta-propiolactone appears superior to other chemicals tried, and satisfactory methods of processing the biologicals have been developed and applied in a relatively large group of patients

Properties of Beta propiolactone

Beta-propiolactone was first synthesized by Johannson[2] in 1915, who used the silver salt of beta-iodopropionic acid, but Beckurts and Otto attempted to make it in 1885 Kung, in 1941, found a method of synthesizing beta-propiolactone from ketene and formalin and assigned the patent to the B F Goodrich Company Since that time the substance has been studied and produced by Gresham and co-workers[3] in the research center of the Goodrich company In 1950, beta propiolactone was furnished to us by Parke-Davis & Company for evaluation in our screening[4] All the beta propiolactone was obtained subsequently through the courtesy of Gresham and the Goodrich company

This chemical is a colorless, stable liquid in its concentrated form, but it is quite unstable in aqueous solutions It is best kept at –20 to –30 C in plastic or neutraglass sealed containers It has a specific gravity of 1 149 and is 37 5% soluble in water at 25 C It reacts readily with hydroxyl, amino, carboxyl, sulfhydryl, and phenolic groups

Beta-propiolactone has been reported[5] as a more effective sterilizing agent for a wide variety of viruses, bacteria, and fungi, including their spores (table 1) Our studies show that sterilization can be attained with concentrations of the chemical that do not denature the plasma and tissue proteins to any objectionable extent This method has already been successfully employed clinically for the sterilization of plasma, sterilization of tissue grafts, and the preparation of virus vaccines

Sterilization of Plasma

Previous publications give, in more detail, the advantages of beta-propiolactone over mechlorethamine hydrochloride (nitrogen mustard), dichlorodiemethyl sulfide (mustard gas), ethylene oxide, the photodynamic action of dyes, or ultraviolet irradiation for the inactivation of numerous viruses artificially seeded in plasma and those naturally occurring in plasma during the stage of viremia[1] Extensive studies from this laboratory also show that a wide margin of safety exists between the virucidal and the toxic concentrations of beta-propiolactone Since the hepatitis viruses have not been successfully studied in the experimental laboratory, the ultimate effectiveness of beta-propiolactone

---

From the Department of Laboratories, Henry Ford Hospital

Read before the Section on Pathology and Physiology at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956 against these agents remains in question Although plasma treated with a 0 6% solution of beta-propiolactone is nontoxic to man upon intravenous administration, this concentration is one and one-half times that necessary to inactivate the most resistant laboratory virus (that of eastern equine encephalomyelitis) and 12 times that necessary to inactivate the most sensitive virus (that of lymphocytic choriomeningitis) when these agents are seeded in plasma However, in order to maintain the integrity of the plasma proteins a 0 45% concentration of beta-propiolactone should not be exceeded Since a concentration of 0 3% of beta-propiolactone in transfusion units of icterogenic plasma is not sufficient to inactivate the last-trace quantities of hepatitis virus present the combination of beta-propiolactone and ultraviolet irradiation previously reported[6] has been extensively studied and the technique for use on large volumes elaborated

Animal experiments with the eastern equine encephalomyelitis virus clearly show that there is always an additive and often a synergistic virucidal effect with beta-propiolactone and ultraviolet irradiation[7]

The maximum degree of virus inactivation can be obtained by the use of a combination of from one-third to one-fourth of the beta-propiolactone concentration and from one-third to one fourth of the ultraviolet irradiation as when either agent is used alone What is more important is the fact that the combination can be used in marked excess of that necessary for sterilization and the integrity of the plasma proteins, as demonstrated by electrophoresis will still be maintained[7] With a wider range between the dosage necessary for sterilization and that bringing about protein alteration, the combination shown here is the most promising available method for inactivating the hepatitis virus in human plasma

Plasma treated with 0 35% solution of beta-propiolactone plus ultraviolet irradiation in the intensity recommended by the National Institutes of Health standards, produces a product that is clear amber in color, keeps for long periods, and is well tolerated by patients Over 100 units of treated plasma has been administered to infants and adults without any untoward, immediate or delayed, reactions

TABLE 1 —*Beta-propiolactone Concentration Required for in Vitro Sterilization of Micropathogens*

Pathogens	No of Pathogen Tested	Sterilizing Concentration of Beta propiolactone Gm /100 Cc
Viruses	8	0 05 to 0 30
Bacteria		
Vegetative forms		0 1 to 0 20
Spore forms	[illegible]	0 5 to 0 75
Fungi		0 25 to 0 50

* Viruses require a lower concentration for sterilization than either bacteria or fungi Spore forms require the highest concentration of beta propiolactone for sterilization

Sterilization of Grafts—Arteries, Bones, and Cartilage

The problems confronting surgeons who are interested in a tissue bank are, first, how to obtain sufficient arteries, bone, and cartilage to meet the demand of todays advanced techniques in surgery and, second when such tissues are available, how to be certain that these are free from infectious micro-organisms Arteries can only be obtained from dead persons by special grants from relatives Bone and cartilage can be obtained from the living in limited quantities, whereas an adequate supply can be obtained from dead persons if there is efficient sterilization

The actual use of tissue grafts sterilized by beta-propiolactone is based on extensive animal experiments[8] Arteries and bones were placed in heavily seeded material, incubated for two hours at 37 C treated, and then transferred to suitable mediums and/or animals to enhance the growth of any micro-organisms that might survive the sterilization

TABLE 2 —*Depth of Tissue Sterilization with One Per Cent Solution of Beta-propiolactone After Bacteremia and Viremia in Susceptible Hosts*

Conditions		Result —Sterilization of Tissue Thickness Mm				Controls	
Pathogen	Susceptible Host	Artery	Bone	Kidney	Liver	Bacterial Count*	Virus Titer†
Escherichia coli	Rabbit	3	6	3	3	8×10^6	
Pneumococcus (type 3)	Mouse	[illegible]		3		9×10	
MM strain encephalomyocarditis virus	Mouse	3	[illegible]	3	3		3 6
Lymphocytic choriomeningitis virus	Guinea pig	3	3	3	3		3 9
Eastern equine encephalomyelitis virus	Rabbit	3	[illegible]	3	3		4 4

* Count per gram of tissue in kidney tissue

† Virus titer LD50 is the reciprocal of negative logarithm (base 10) of virus dilution Tissue sterilization can be accomplished at a depth of 3 mm or less for compact tissue and up to 6 mm for cancellous bone In virus studies thickness of bone did not exceed 3 mm

In a second group of experiments, tissue slices were obtained from infected animals during the stage of bacteremia or viremia[9] These specimens included arteries, bone kidney, and liver ranging from 1 to 9 mm in thickness which were treated with 1% solution of beta-propiolactone (table 2) The bone samples were sawed from ribs giving an outer, thin compact layer and the cancellous inner portion

Tissue treated with 1% solution of beta-propiolactone appears well preserved upon microscopic examination However its failure to grow in tissue culture shows it is not viable It has been found that certain tissues need not be viable to function temporarily The nonviable tissues that have proved acceptable are arteries, bone, and cartilage providing they are nonantigenic and sterile

From October, 1954, to March, 1956, arteries sterilized with beta-propiolactone have been used at the Henry Ford Hospital in 120 operations with good results[10] This use was preceded by two years of experimental work in dogs[8] Since July, 1955, bone and cartilage have been used in over 30 operations with equal success

Antigenicity of Beta-propiolactone-Inactivated Virus Vaccines

In the preparation of inactivated virus vaccines, the margin between complete inactivation and the amount of antigenicity retained is so narrow that the search for more satisfactory methods has been intense In a previous report[11] and in studies in progress, beta-propiolactone appears to have advantages over other chemicals for the preparation of inactivated virus vaccines

It inactivates viruses completely and irreversibly in from 10 to 15 minutes at 37 C, whereas inactivation with formalin and phenol requires several days under the same conditions Beta-propiolactone can be added in excess of the minimal, effective, virucidal concentration with a margin of safety between the complete inactivation of viruses and loss of antigenicity Moreover, significantly higher degrees of antigenicity have been obtained with beta-propiolactone-inactivated virus vaccines than with phenol-inactivated or formalin-inactivated vaccines under parallel conditions

Formalin-inactivated and phenol-inactivated viruses of murine encephalomyocarditis, eastern equine encephalomyelitis, and rabies were compared with the same viruses inactivated with beta-propiolactone Formaldehyde (0 12% solution) inactivated the MM virus in 24 hours, while beta-propiolactone (0 2% solution) inactivated the same virus in 10 minutes No antigenicity titer could be demonstrated for the formalin-treated MM material, while material treated with a 0 2% solution of beta-propiolactone gave a titer of 10^{-2} Phenolized rabies virus gave a resistance index of less than 10 as compared with a resistance index of 125 in material treated with a 0 2% solution of beta-propiolactone Treatment with beta-propiolactone also gave an antigenic response with MM virus almost as high as with the live virus These results have been confirmed by other investigators[12]

Summary

Beta-propiolactone is a superior sterilizing agent for biologicals because of its rapid and irreversible action minimal alteration of proteins, and complete hydrolysis, obviating neutralization and toxicity Preservation of proteins and relatively nontoxic end-products of hydrocrylic and beta-chloropropionic acids makes beta-propiolactone the most promising chemical for the sterilization of blood plasma Rapid killing of bacteria and inactivation of viruses with maintenance of comparatively high antigenicity offers a method for the production of improved vaccines Activity on a wide variety of bacteria, fungi, and viruses, coupled with rapid penetration of tissues, opens the way for safer and more plentiful homogeneous tissue grafts of arteries bone, and cartilage

Hypertension —Effective treatment of hypertensive emergencies requires an agent which will reduce the blood pressure quickly and effectively It is fortunate that a choice of drugs is available at this time However, the potency of many of these agents is such that an intimate knowledge of pharmacodynamics of them is necessary if they are to be employed with maximum efficiency and safety The very potency of many of these agents makes them dangerous if improperly employed Marked elevation in blood pressure itself, even though due to many different causes, may become a direct threat to the patient s life if not brought under immediate control This is so even though the elevated blood pressure may be only a part of the clinical syndrome Under these circumstances control of the blood pressure can become the primary therapeutic problem and, in fact, can become a life saving procedure The more important disease entities in which hypertension can become an emergency are acute nephritis, toxemia of pregnancy, hypertensive encephalopathy, pheochromocytoma, fulminating heart failure due to essential hypertension, hypertensive crisis, cerebral hemorrhage with severe hypertension, renal artery occlusion and others —J H Moyer, M D, and E W Dennis, M D, Treatment of Hypertension, *Southern Medical Journal*, June, 1956

INDUCED HYPOADRENALISM IN PATIENTS REQUIRING ORTHOPEDIC SURGERY

James A Nicholas, M D , Philip D Wilson, M D
and
Charles J Umberger, Ph D , New York

• *Prolonged administration of steroids often, but not always, results in adrenocortical insufficiency It has been difficult to determine whether a patient so treated is actually devoid of adrenocortical function Elective surgery on bones and joints in such a patient should be postponed until his adrenal status is ascertained and he has been weaned away, if necessary, from the steroid The test used for this purpose consists in administering corticotropin and determining daily salt excretion during a period of constant salt intake, hypoadrenalism is likely to exist if the corticotropin fails to reduce the salt excretion and especially if it fails to induce eosinopenia and hypokalemia Ten patients who had been receiving steroids (for seven years, in one instance) underwent orthopedic surgery The above test was carried out in nine and revealed adrenal insufficiency in six The diagnosis was borne out by the occurrence of shock in four of the patients and the effectiveness of hydrocortisone given intravenously in combating it In cases of elective surgery the operation can be postponed for several months to permit weaning, but, when emergency surgery is required in a patient who has been receiving cortisone, increased amounts of steroid will be needed during and after the operation*

Hypoadrenocorticism is increasing in frequency because of the increased variety and use of steroids in the treatment of a number of diseases This has produced a growing problem for those of us who are called on to operate on such patients for injury or reconstruction of their bones and joints [1] Orthopedic surgeons in particular should be cognizant of the symptoms and management of sudden adrenocortical insufficiency during and after surgery or injury, since a number of patients who receive cortisone acetate or other steroids come under their treatment for reconstruction

Hypoadrenocorticism may result from several conditions It may be induced by the administration of steroids It results from adrenalectomy or hypophysectomy, procedures in vogue today for treatment of certain cancers, from hyperplasias of the pituitary adrenal system, and from hypertension It occurs in adrenal cortical hypofunction (Addison's disease) Finally, it may occur as a result of adrenal tuberculosis, amyloid disease, and other pathological conditions of the adrenals

Effect of Long term Use of Steroids

There are many corticosteroids on the market today Among them are cortisone, hydrocortisone, fludrohydrocortisone acetate, prednisone (Meticorten), prednisolone (Sterane), Co-Deltra (buffered prednisone), and Co-Hydeltra (buffered prednisolone) Other preparations, which include salicylates (such as Sigmagen [tablets containing prednisone, aspirin ascorbic acid, and aluminum hydroxide] and Salcort [tablets containing cortisone acetate, sodium salicylate, dried aluminum hydroxide gel, calcium ascorbate, and calcium carbonate]), are also being widely used Some confusion has been produced among doctors and patients alike by the variety of trade names for the identical steroid The fewer side-effects these steroids have, the more widely they are used However, one side-effect that has not been diminished is induced hypoadrenalism, which may result from therapy with steroids over a long period of time That these steroids are potential adrenal suppressors, causing functional and pathological adrenal atrophy, has been well established by Bennett [2] and others [3]

Diagnosis of Hypoadrenalism

Patients with hypoadrenalism who must undergo surgery may be classified into two categories First, they may have adrenocortical insufficiency but their operation may be classified as elective It can be put off until the appropriate time Second, they may have adrenocortical insufficiency at a time when injury or disease requires an emergency operation The diagnosis of hypoadrenalism in each of these cases is a difficult problem

Elective Cases —When faced with the problem of operating on a patient in whom he suspects adrenocortical insufficiency, the surgeon would like to know whether this condition actually is present Adrenal insufficiency may not be provoked until a very major stress occurs, such as an operation of great magnitude It also may occur, however, with a far less stressing incident, such as a simple manipulation of the knee with the patient under anesthesia [4]

We have had difficulty in determining whether the patient who has been receiving steroids for some length of time is actually devoid of adrenocortical function One of the indicators we have been studying is the measure of salt conservation after an intravenous infusion of corticotropin (ACTH) The amount of salt excreted in the urine per 24 hours is measured for 48 hours, during which time the salt intake is calculated and restricted to not over 3 Gm per 24-hour period During this time blood electrolytes as well as the 24-hour urinary potassium and sodium excretion are measured After the 48 hours have passed, an infusion is given of 50 mg of corticotropin in 500 cc of dextrose and water over a 4-hour period Thereupon, in the next 24 hours, at 12-hour and 24-hour periods the total uri-

From the Hospital for Special Surgery the Margaret Caspary Research Department, Cornell University Medical College

Read before the Section on Orthopedic Surgery at the 105th Annual Meeting of the American Medical Association, Chicago June 13 1956 nary salt excretion is recorded as well as the blood electrolytes If the patient has normal adrenal function, the amount of salt excreted in the urine in the 24 hours after this test will decrease by 50 to 75% of that in the control period Since the average person normally excretes about 100 mEq of salts a day per liter of urine, usually the excretion in the urine will not exceed 40 or 50 mEq per liter over the 24 hours after the infusion Therefore, if the amount excreted fails to decrease, this failure to conserve salt after the test with corticotropin should alert one to the possibility of hypoadrenalism This condition is especially likely to exist if the patient also fails, after the infusion of corticotropin, to develop hypokalemia, a slight rise in the plasma level of 17-hydroxycorticoids, and a transient eosinopenia, all of which occur in the normal person The absence of these particular changes in response to corticotropin provides a useful indicator that supportive steroid therapy may be required Clinically, the presence of asthenia and hypotension is doubly significant, especially if the patient has received adrenocortical steroids for over three months

We have used this method of assay in nine patients, and we have been able to demonstrate to our satisfaction, prior to surgery, the need for supplementary treatment during stress in six patients The successful treatment of these six patients with supportive therapy indicates either that this method of assay was useful or that the administration of corticosteroids did not harm the patient in the recovery from stress even if the supplementary steroid was not actually needed The three patients in whom the preliminary tests disclosed salt conservation after infusion of corticotropin, despite long-term treatment with cortisone, received no supplementary steroids and tolerated surgery without difficulty

Emergency Cases —A second problem, which is difficult to evaluate, occurs in the patient who must have emergency operation or treatment due to injury and in whom there may be some deficiency in pituitary or adrenal function In this instance, one is not able to examine the patient elaborately prior to surgery, and, consequently, we have found that a regimen similar to that described recently by Perlmutter[5] has been of some help to us in the subsequent management In such cases, where a history of cortisone therapy has been given, the simultaneous examination of a specimen of voided urine and of blood for sodium concentration will be useful A high degree of salt excretion and a low serum sodium level should suggest the possibility of hypoadrenalism and alert the surgeon to the need for treatment in the event of shock In emergency cases, the presence of eosinophilia, unexplainable hypotension and a high urinary volume and salt excretion indicates adrenal insufficiency

Present Series

We have collected the data on 10 patients requiring operations on the bones and joints (see table) All of the patients had been receiving cortisone or other steroids for at least four months prior to surgery One of them had also been receiving desoxycorticosterone acetate (Doca) pellets for seven years because of adrenal cortical hypofunction Two of the patients had been receiving prednisone and two, hydrocortisone orally Three additional patients were suspected of having adrenal insufficiency because of long-term corti

Occurrence and Treatment of Adrenocortical Insufficiency in Ten Orthopedic Patients Undergoing Elective or Emergency Surgery

Case No	Surgery	Age Yr	Sex	Diagnosis	Steroid Used Previously	Operation	Supplementary Management	Shock	End Result Time After Surgery
1	Elective	43	M	Pemphigus 2½ yr (osteoporosis avascular necrosis hip)	Cortisone acetate 35-1 000 mg (av 200 mg daily)	Replacement of head of femur	Cortisone salt blood	9 times in 72 hr	Living and well 4 yr
2	Elective	37	M	Adrenal cortical hypofunction (Addison disease) arthritis lumbosacral and sacroiliac joints	Desoxycorticosterone acetate (Doca) pellets 150 mg cortisone 25 mg 7 yr	Spinal fusion and sacroiliac fusion removal of plate (4 mo later)	Desoxycorticosterone cortisone hydrocortisone I V saline solution blood	none	Wound infection living and well 2 yr
3	Elective	60	M	Rheumatoid arthritis protrusio acetabuli	Cortisone mg 18 mo hydrocortisone 20 mg (stopped 3 wk prior to surgery)	Angulation resection osteotomy hip	Hydrocortisone I V cortisone prednisone (Meticorten) blood	none	Living and well 4 mo
4	Elective	57	M	Rheumatoid arthritis (severe contracture)	Hydrocortisone orally 20 mg daily 2 yr	Femoral osteotomy	Cortisone hydrocortisone I V blood	none	Living and well 18 mo
5	Elective	68	F	Rheumatoid arthritis intracapsular fracture nonunion (osteoporosis)	Hydrocortisone orally 20-40 mg 4 mo	Smith Petersen nailing Fred Thompson prosthetic replacement 6 wk later	Cortisone hydrocortisone prednisone blood	twice	Living and well 18 mo
6	Elective	54	M	Rheumatoid arthritis fracture of right hip nonunion	Hydrocortisone cortisone 50-100 mg 3 yr	Prosthetic replacement right hip	Hydrocortisone I V cortisone I M blood	none	Living and well
7	Emergency	56	M	Rheumatoid arthritis ruptured appendix (fistula [fecal] sepsis osteoporosis)	Cortisone 50 mg I M hydrocortisone intra arterially 18 mo	Appendectomy closure evisceration (2 wk later)	Hydrocortisone I V cortisone saline solution blood	3 times in 24 hr	Death (adrenal atrophy and sepsis)
8	Emergency	78	F	Rheumatoid arthritis (osteoporosis) intracapsular fracture of hip	Prednisone 20 mg 8 mo	Smith Petersen nailing of hip	Hydrocortisone I V cortisone prednisone blood	twice	Living and well 6 mo
9	Emergency	45	F	Idiopathic thrombocytopenic purpura intracapsular fracture of hip osteoporosis	Prednisone 40 mg 6 mo 10-40 mg	Knowle pins hip	Cortisone prednisone blood	none	Death 4 mo (autopsy showed normal adrenals)
10	Emergency	48	F	Osteoarthritis intracapsular fracture of hip	Prednisone 20-30 mg 9 mo hydrocortisone	Smith Petersen nailing of hip	Prednisone hydrocortisone I V	none	Living and well

sone therapy, but they did not demonstrate this condition in response to the test with corticotropin They are not included in this study

It was of great interest to note the preoperative conditions that required treatment with steroids Six persons were afflicted with rheumatoid arthritis of advanced degree, one had pemphigus, one had idiopathic thrombocytopenic purpura, one had adrenal cortical hypofunction, and one had been receiving cortisone for osteoarthritis None of the patients had received corticosteroids for less than four months Dosages ranged anywhere from 20 mg of prednisone a day for four months to 1,000 mg of cortisone a day over two years Two patients died one directly as a result of adrenal insufficiency and treatment, the other four months later of other causes We have been able to examine the adrenals of both of these patients The autopsy of the patient who died soon after operation disclosed adrenal atrophy, with both adrenals weighing less than 3 Gm There were thin cortices, with loss of the lipid substance However, in the patient with thrombocytopenic purpura who died four months after operation, the adrenals appeared normal despite the patient's having received heavy doses of prednisone for over six months up to the time of death

Six of the patients thought to have induced hypoadrenalism underwent elective surgery and four underwent emergency surgery Three of the four undergoing emergency surgery required open treatment for fractures, while the fourth, with arthritis, developed a silent ruptured appendix Operative procedures performed on the patients included insertion of Knowles pins and Smith-Peterson nails, spinal fusion, osteotomy, resection-angulation osteotomy, and prosthetic replacement of the head of the femur The ages ranged from 36 to 78 years

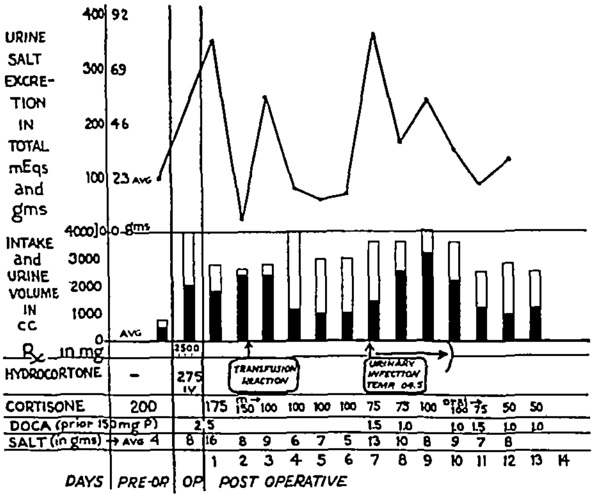

Fig 1 —Salt loss and treatment in patient with adrenal cortical hypofunction (Addison's disease) undergoing spinal fusion

Treatment consisted of increasing the amounts given of steroids in various forms and, in some cases, of salt administration during surgical stress and shortly thereafter One patient also received desoxycorticosterone Details of management varied, depending on the particular time these patients were studied For example, in 1952 a patient was carried through simply with intramuscular administration of cortisone every four hours and with salt, whereas the last patient was given cortisone intramuscularly before, hydrocortisone intravenously during, and prednisone after surgery In only one case, because of adrenal cortical hypofunction, was it necessary to use desoxycorticosterone In this patient, after a spinal fusion, a transfusion reaction and a urinary tract infection produced a sharp increase in salt excretion requiring the use of additional desoxycorticosterone, salt, and cortisone Figure 1 illustrates the rise in urinary salt excretion and the need for supplementary steroids in this patient

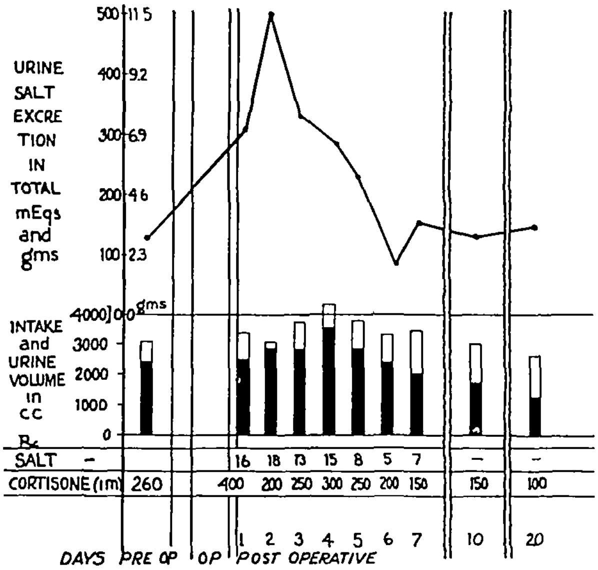

Fig 2 —Salt loss and treatment in patient with induced adrenal insufficiency undergoing replacement of head of femur

Follow-up of these patients varies from six months to four years In no instance after convalescence has there been any evidence of further adrenocortical insufficiency Except during periods of stress, practically all the patients were receiving low maintenance doses or no steroids whatsoever when last seen

Clinical Response During Early Postoperative Period—Shock occurred in 4 of the 10 patients postoperatively (This was defined as blood pressure under 80/50 mm Hg, pulse rate over 120 per minute, and clinical appearance of shock) The first patient we studied, who had pemphigus, had nine separate bouts of shock within 72 hours postoperatively, requiring heroic, constant treatment Undoubtedly, in this patient shock was due to frank insufficiency as well as to poor management The fact that this patient's urinary salt excretion was excessive can be seen in figure 2 One patient died despite all attempts at therapy Within three weeks this patient had had three separate bouts of shock Death was due to sepsis and overwhelming infection as well as to adrenal atrophy One patient, who had undergone an uncomplicated Smith-Petersen nailing, had two separate bouts of shock 24 hours after operation A second patient had two separate bouts of shock within the first 24 hours after replacement of the head of the femur The intravenous use of hydrocortisone in both of the last-mentioned patients was effective in restoring blood pressure to normal All of the patients operated on received adequate blood transfusions In none of the patients was hemorrhage the cause of shock Particular care was taken to maintain blood volume It was interesting to note that in no instance was shock present while the patient was under anesthesia, it occurred only after the patient had awakened The shock would come on in a matter of minutes and lasted in one case, as long as two hours Usually, marked improvement was noted within a half-hour after administration of hydrocortisone In addition, each of the four patients in whom shock developed had eosinophilia and an unusually high salt excretion for a number of days after surgery This, to us, was significant evidence that there was a defective adrenocortical response to the stress of surgery or injury In no instance was there evidence of renal disease or water intoxication

Treatment

The hypotensive state may come when one expects it least, namely, during the first 24 to 48 hours postoperatively It comes on with great speed and requires definitive treatment One cannot wait for corroboration by the laboratory in such cases The treatment of adrenocortical insufficiency with a corticosteroid is most important Even if one is not certain in such an emergency that the hypotension is due to adrenal depletion, we feel that hydrocortisone should be given intravenously along with other supportive treatment A high eosinophil count in the presence of severe stress (with a high amount of urinary salt excretion), as well as persistent tachycardia and hypotension despite adequate blood replacement therapy, is an indication that adrenocortical insufficiency is present We feel that the treatment of induced adrenocortical insufficiency can proceed along three lines

1 Patients undergoing emergency surgery should receive 100 mg of hydrocortisone intravenously in 500 cc of saline solution, supplementary blood, and cortisone intramuscularly in 50-to-100-mg doses 2 Patients undergoing elective surgery who require cortisone up to the time of surgery should be treated as follows Preoperatively, they should receive 100 mg of cortisone at 9 p m the evening before and at 7 a m the morning of operation During operation, they should receive 100 mg of hydrocortisone in addition to blood Postoperatively, they should receive, every 12 hours, 50 to 100 mg of cortisone the first day and 25 to 50 mg the second day Then, if the course is satisfactory, prednisone should be substituted on the third day and given daily in 20-mg doses for three days, and the doses should then be tapered off 3 For patients undergoing elective surgery who do not require steroids, the surgery should be put off for three months while steroid administration is tapered off and the patient's adrenal function is studied

Response to the first two regimens described indicates that the assumption of adrenocortical insufficiency is correct, although actual proof of this may be difficult However, we feel that, since it is only a short-term method of treatment bolstered by continuing intramuscular administration of steroids, the danger of infection or failure in wound healing is quite remote This is particularly true in operations on extremities, where sepsis is less catastrophic, rather than in operations on the intestine However, high doses of cortisone will interfere with repair, and, therefore, one should take the patient off this regimen as quickly as possible[6] In this particular series, infection occurred in only one patient, when pyelitis, cystitis, and wound infection developed in the patient with adrenal cortical hypofunction

Long-term prednisone therapy did not produce pathologically detectable adrenal atrophy in the patient with idiopathic thrombocytopenic purpura, who came to autopsy Whether functional atrophy was present is not known, as this patient was operated on for a fracture and was not studied preoperatively

Summary and Conclusions

There are a great many steroids on the market today that may cause adrenocortical insufficiency if they have been used for a long time prior to surgery It is important to know whether adrenocortical insufficiency occurs, as it produces shock and is easily manageable Therefore, each patient should be closely questioned for pretreatment with a corticosteroid The use of a salt-excretion test after infusion of corticotropin has been of some value preoperatively as an indicator of adrenocortical insufficiency and, thus, of the need for supplementary treatment

Ten patients who had been receiving cortisone acetate for a sufficient amount of time to produce in some of them adrenocortical insufficiency underwent operation In six of nine patients in whom a preoperative test with corticotropin was utilized, the failure to conserve salt in addition to the failure to develop eosinopenia indicated the need for supportive therapy, and these patients were managed on such a program during surgery with a minimum of discomfort One patient on long-term corticosteroid therapy did not present evidence of adrenocortical insufficiency at autopsy, while still another did produce evidence of this Accordingly, adrenocortical insufficiency often, but not always, results from prolonged administration of steroids

One should test for adrenocortical insufficiency rather than take its presence for granted prior to surgery Operations on any patients undergoing elective procedures on the bones and joints should be postponed, therefore, until an assay to rule out adrenocortical insufficiency has been undertaken A patient who has been receiving cortisone or another corticosteroid for any length of time and who requires surgery should be weaned away from the steroid for several months and then have surgery performed When a patient has been receiving cortisone, however, because of other factors and when emergency surgery is required, treatment should consist of administration of increased amounts of cortisone and hydrocortisone during and after surgery, as needed, until the patient's condition becomes stable

THE NATURAL HISTORY OF HERPES ZOSTER

Carroll F Burgoon Jr , M D , Jane S Burgoon, M D , Philadelphia
and
G Douglas Baldridge, M D Los Angeles

• *The course of herpes zoster was studied in a series of 206 patients that included infants and octogenarians There were 32 patients under the age of 20 in 30 of these (94%) the condition cleared up in 14 days or less The infection was more severe and prolonged in older patients In four elderly patients symptoms persisted six months or longer The relative frequency with which the various parts of the nervous system were involved varied from youth to old age No instance of involvement of the ophthalmic division of the trigeminal nerve was observed in patients under the age of 20, but ocular complications did not appear to be related to the aging process Postherpetic neuralgia did not occur in patients under 20 but was frequent in patients over 50 Sex, race, and season did not perceptibly influence the incidence of infection in this series*

Herpes zoster is an acute, self-limited disease of infectious origin It is characterized by grouped vesicular lesions on an erythematous base distributed over several dermatomes as well as, in some cases, by a systemic reaction This study of the incidence, duration, distribution, and complications was undertaken to establish clearly the natural history of the disease Impressions gained from the more severe reactions associated with herpes zoster have tended to color the picture unfavorably As a result of these impressions, the literature is crowded with many reports of treatments advocated to alleviate pain and shorten the course of the infection Jadassohn[1] suggested the benign nature of herpes zoster in his review, but, until recently no attempts have been made to chart its natural course It is hoped that this study will serve as a yardstick to evaluate the future claims for therapeutic success in patients with this infection

The majority of the 206 cases for this analysis were chosen from the dermatology and ophthalmology departments of a general hospital (Hospital of the University of Pennsylvania, Philadelphia) and the outpatient department of a pediatric hospital (Children's Hospital of Philadelphia) over a 15-year period By surveying a pediatric hospital and an ophthalmology clinic, we naturally increase the number of children and the incidence of ophthalmic involvement We felt that this would give a more valid picture of the infection than a study of cases selected from a dermatology clinic alone, and that this was a valid assumption is shown by a comparison of the age groups in our series with the percentage of the population of Philadelphia in the various age groups

In analysis of the data the number of cases in the study of any one facet of the infection varies according to the information that was available on the various cases The infection was considered to have cleared when all crusts had fallen off leaving erythematous, macular lesions The postinfectious inflammatory reaction on the skin was not considered part of the acute infection in the evaluation of the length of the infection Neuralgia following herpes zoster was defined as any subjective, painful sensation that persisted after the acute phase of the infection Treatment consisted of a number of nonspecific measures and, therefore, did not enter into the data

Etiology

Virological studies have established clearly the similarity of the infectious agents in chickenpox and herpes zoster The elementary bodies seen under the electron microscope are rounded or brick-shaped and measure approximately 210 by 243 mμ They are most numerous during the first 12 to 24 hours and decrease rapidly so that by 72 hours they are practically nonexistent The virus particles from chickenpox and herpes zoster are indistinguishable in all physical appearances Von Bokay[2] suggested the close relationship between the two after observing cases of chickenpox arising after contact with herpes zoster Since then, many reports of chickenpox occurring in persons who are in contact with patients with herpes zoster have been reported, while the reverse has been much less commonly observed In this connection, the British medical research council reported 20 outbreaks of chickenpox instituted by cases of herpes zoster in boarding schools for boys during a five-year period

Read before the Section on Dermatology at the 105th Annual Meeting of the American Medical Association Chicago June 12 1956

Kundratitz[3] and Bruusgaard[4] have observed that the intradermal injection of fluid from fresh vesicles of herpes zoster in children under 6 years of age will produce localized lesions of clinical chickenpox in 9 to 12 days after inoculation All adults and children with a previous history of chickenpox fail to develop lesions after inoculation Complement-fixation reactions with herpes zoster fluid or chickenpox crusts as an antigen and convalescent serum show cross fixation of complement between the two diseases In addition, convalescent serum produces cross agglutination of elementary bodies under the electron microscope

Herpes zoster is classified as spontaneous (primary) or symptomatic (secondary) depending on whether or not there is a predisposing factor The majority of cases are of the primary variety, in which no known causative factor triggers the infection

In this series, one case of herpes zoster was associated with a lymphoblastoma In addition, symptomatic (secondary) herpes zoster has been recorded occurring after a variety of traumas, these include spinal puncture, intramuscular injections, x-ray therapy, and administration of arsenic The present study does not suggest a statistically valid correlation with any trigger mechanism However, the possibility that traumatic factors may activate a latent virus is suggested by the observation of 16 cases of herpes zoster among 406 patients with carcinoma of the breast (12 of the 16 had metastases)[5]

No information concerning the incubation period of the virus was obtained from the analysis of the data The most valid information concerning this is provided by the human inoculation experiments in which a period of 7 to 14 days elapsed between the injection of herpes zoster fluid and the production of a reaction[6]

Clinical Picture

Herpes zoster infections may generally be divided into three general groups, according to the symptoms (1) those associated with involvement of the cutaneous system, (2) those associated with involvement of the nervous system, and (3) those associated with a generalized systemic response to the infection

The skin lesions typically appear first as erythematous papules, which progress to vesicles within 12 to 24 hours and to pustules in 72 hours When pustulation appears, the surrounding erythema begins to subside, and in seven to eight days the pustules begin to dry Crust formation occurs in 10 to 12 days, and the crusts fall off in 2 to 3 weeks In very mild infections, the cutaneous lesions may remain as erythematous maculopapules and rapidly regress within 7 to 10 days without vesicles appearing In an occasional case, the cutaneous reaction is so severe that the lesions become gangrenous and weeks are required for complete healing The cutaneous reaction characteristically involves one or more dermatomes spreading in a band-like manner Unilateral segmental involvement is the rule, although bilateral involvement does occur The latter occurred in less than 0 5% of the cases in this series The grouped vesicles frequently appear on the skin over the proximal portion of the involved nerve root and spread distally The thoracic segments are most frequently involved, but any area of the skin or mucous membrane may be affected

Involvement of the nervous system was associated with some variety of pain in 66% of the patients in this study The pain associated with the infection may appear as a prodromal symptom, during the acute infection, or after the inflammatory reaction on the skin has subsided It is usually categorized by the patient as pruritic, stabbing, burning, or aching in nature and can be constant or intermittent The pain is evanescent in most patients but is quite persistent in others and seems to bear no relation to the severity of the skin involvement Prodromal pain is not uncommon four to five days prior to the skin changes, but occasionally a segmental burning pain lasts for 10 to 14 days without obvious skin lesions On close inspection, a faint macular erythematous eruption may be seen as the only cutaneous manifestation, although the regional lymph nodes are usually enlarged and tender

Systemic response to the infection usually consists of headache malaise, nausea, temperature elevation stiff neck, and regional lymphadenopathy In this study, a systemic reaction was observed in 5 8% of the cases In our experience, this type of response is more common in the pediatric age group, only one of our patients with this reaction was an adult

Two patients gave a history of previous episodes of herpes zoster, one occurring in the same distribution Interpretation of the history is difficult because of the occasional tendency of herpes simplex infection to have a zosteriform distribution Four patients (2%), aged 55, 62, 72, and 82 years, developed a generalized vesicular eruption The eruption was associated with different segments (ophthalmic, cervicothoracic, lumbar) The vesicles appeared over a 48-hour period in two patients and cleared in two weeks, while in the third patient, aged 72 years, the vesicles appeared over a seven day period and the eruption required five weeks to clear From this study, we conclude that herpes zoster generalisatus is uncommon and appears to be most frequent in older age groups

Incidence

We have made no attempt to evaluate the percentage of cases of herpes zoster in the total number of admissions to a dermatology clinic We suspect, however, that the infection is significantly more common than the reported frequency of 0 5 to 2% The layman can easily make the diagnosis, and many persons with the disease never seek medical care

Results similar to those that we would expect in a study of the true incidence of herpes zoster infection were obtained in the study of the incidence of herpes simplex in 1,000 families In that study,[7] the actual incidence of apparent infection in the families studied was found to be 15%, in contrast to less than 1% incidence in the total number of patients seeking medical care in an outpatient study

Climate —No climate nor country seems to be free from herpes zoster Some reports have suggested a seasonal variation in the incidence of infection In an analysis of our cases, we found no statistically valid difference in incidence in any of the four seasons Simons[8] was unable to show any climatic influence in an extensive study on the incidence of infection in Europe and the tropics

Sex—Some studies have suggested that the infection is slightly more common in males than in females, but this series shows no significant difference in incidence Of the 206 patients, 50 7% were males and 49 3% females as compared with the total population in Philadelphia of 48 3% male and 51 7% female

Age—In all previous studies in which the relation between age and frequency of infection were considered, the incidence of infection fell off markedly after the age of 60 However, when the incidence in various age groups is correlated with the population distribution in those age groups, our study indicates that this apparent decrease with increasing age is actually an increase (fig 1)

Race—Our study would indicate that there is no apparent difference in incidence of the infection in white and nonwhite population One might expect that, since this is a study of clinic patients in Philadelphia, there would be an overly large number of patients in one group, however, correlation of our group with the percentage of population in each group in the city of Philadelphia shows that we had a normal racial distribution among our patients Of 111 patients, 81 8% were white and 18 1% were nonwhite as compared with the total population of Philadelphia of 81 9% white and 18 2% nonwhite

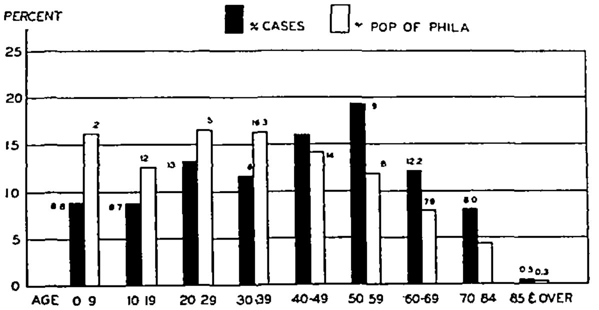

Fig 1—Incidence of herpes zoster by age groups compared with Philadelphia population distribution in each group

Appearance and Distribution of Vesicles

The severity and duration of an infection can be postulated if one observes the number of days over which new vesicles appear Generally, the crusts fall off in from two to three weeks, depending upon the severity of the local destruction In our group of 206 cases, the local reaction was so severe in two cases as to produce a superficial type of gangrene Both of these patients were 60 years old and had no known systemic disease

Of this series of patients, 156 were analyzed as to the number of days over which crops of vesicles appeared In 26 1% of the cases, all of the vesicles appeared within the first 24 hours, in 35 9%, in 48 hours, in 12 9%, in 72 hours and in 12 9%, in 96 hours, in the remainder they continued to appear up to as long as seven days There was good correlation with the duration of the lesions in that (1) if all of the vesicles appeared in the first 24 hours, the eruption cleared in 10 to 13 days, (2) if they all appeared in the first 48 hours, the eruption cleared in 14 to 16 days, and (3) if the vesicles continued to appear for seven days, the eruption continued up to five weeks (fig 2)

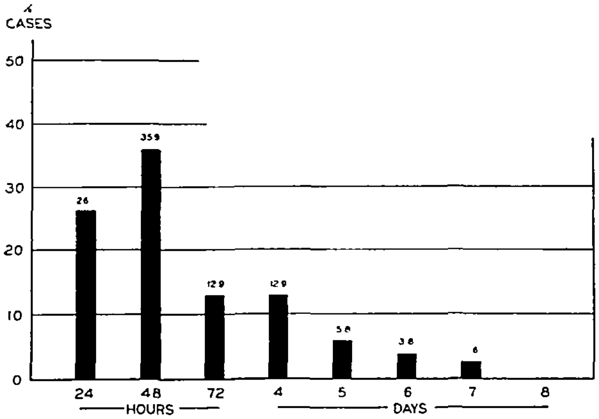

Fig 2—Periods of time and percentage of cases (156) in each period within which all vesicles appeared

In 183 cases, the relation of age to the severity of the cutaneous reaction was studied to determine whether they were significantly related and whether age influenced duration. There were 32 patients in the infant-to-19 year age group Of these, the lesions of 30, or 94%, cleared in 7 to 14 days There were 70 patients in the 40-to-59-year age group Of these, the lesions of 34, or 49%, cleared in 7 to 14 days, 9, or 13%, in 15 to 20 days, 15, or 21%, in 21 to 28 days, and 8, or 11%, in 29 to 55 days, the lesions of the remaining 4, or 6%, lasted longer than 55 days (fig 3) From these figures, it can be seen that the severity of the infection is greater in the older age groups and that, therefore, the duration is longer

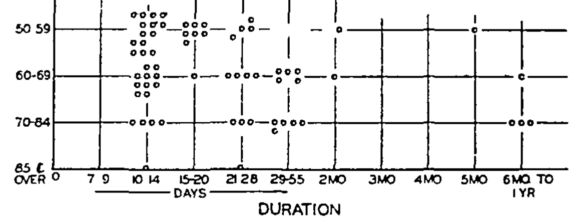

Fig 3—Duration in days and months from onset to clearing of all symptoms of herpes zoster in 183 patients in various age groups

Duration and Distribution

The duration of the infection was determined in 183 cases wherein the duration of the infection was considered to be the period from onset to clearing of all symptoms In this group, 163 patients, or 89.1%, were clear of all skin lesions within five weeks Of these 163, the condition in 2.7% cleared in 7 to 9 days, in 54.6%, in 10 to 14 days, in 9.7%, in 15 to 20 days, in 15.3%, in 21 to 28 days, and in 6%, in 28 to 35 days (fig 4) The remaining 20 patients, or 12%, had pain that persisted after the crusts had fallen off

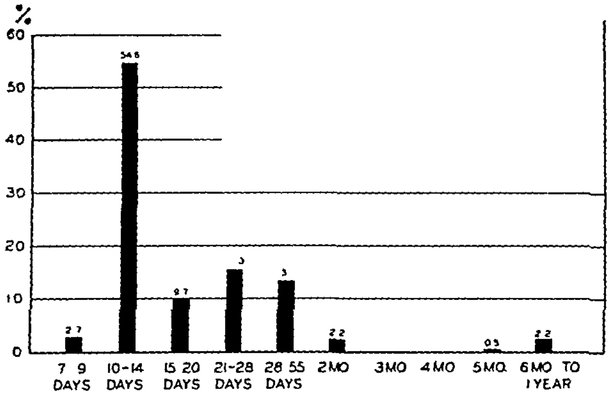

Fig 4—Duration in days and months from onset to clearing of all symptoms of herpes zoster and percentage (of 183 cases) in each duration period

A number of reports have indicated the approximate frequency of the sites involved by herpes zoster Although they all agree as to the frequency of distribution, none has related the frequency of the site of involvement to the age groups We analyzed 204 cases for frequency of distribution and correlated the distribution with age

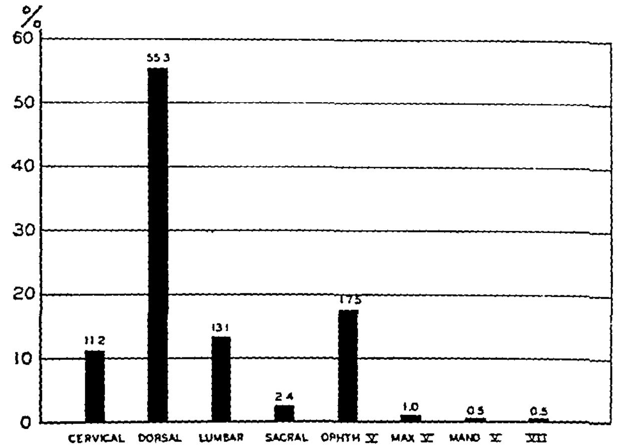

Fig 5—Data from 206 cases on distribution of herpes zoster in regard to involvement of nervous system

The data on distribution in regard to involvement of the nervous system were essentially in agreement with data in previous studies cervical, 11.2%, thoracic, 55.3%, lumbar, 13.1%, sacral, 2.4%, ophthalmic, maxillary, and mandibular divisions of the fifth cranial (trigeminal) nerve, 17.5%, 1.0%, and 0.5% respectively, and the seventh cranial (facial) nerve, 0.5% (fig 5) The high incidence of ophthalmic involvement is at variance with other studies but can be accounted for by the inclusion of the cases from the eye clinic In this analysis, cervicothoracic and lumbosacral were recorded under each distribution There were four patients with cervicothoracic, one with lumbosacral, and none with thoracolumbar involvement

Since age appeared to play a part in the site of involvement, the distributions in the age groups between infancy and 19 years and between 40 and 59 years were analyzed In the 37 patients under 20 years of age, the nerve involvement was either lumbar or thoracic in 89%, cervical in 3%, and maxillary in 1% (fig 6) In the 75 patients in the 40-to-59-year age group the involvement was either lumbar or thoracic in 65.4%, cervical in 10.7%, sacral in 1.3%, ophthalmic in 20%, maxillary in 1.3%, and mandibular in 1.3% There did not appear to be any relation between distribution of nerve involvement and the development of postherpetic neuralgia

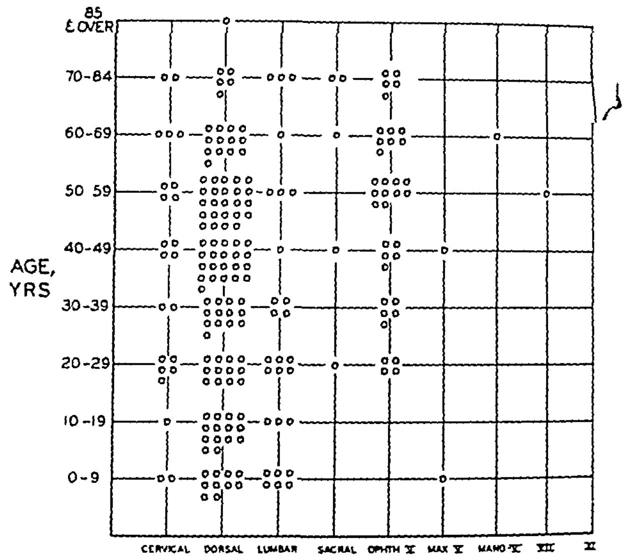

Fig 6—Distribution of nerve involvement among various age groups

Complications

Untoward reactions associated with herpes zoster infections are relatively uncommon, there were 35 cases (16.9%) in this series A number of complications have been reported accompanying this infection They are as follows a superficial type of gangrene, postherpetic neuralgia, endocarditis, meningoencephalitis, paralysis of motor nerves, corneal ulcers, keratitis, and iritis

In our study, postherpetic neuralgia was the most common complication, occurring in 20 cases (9.7%) This is a rare problem in the patient under 40 years of age It occurred in only one patient in the 20 to 29 year age group and lasted only six weeks The distribution of the remaining 19 cases of postherpetic neuralgia and the duration of the disorder were as follows (1) 40-to-49-year age group, one (5%), lasting two months, (2) 50-to-59-year age group, four (20%), lasting two, three, four, and six months respectively,

(3) 60 to 69-year age group, seven (35%), with one lasting one month, two, two months, three, three months, and one, six months, (4) 70-to-85-year age group, six (30%), with one lasting one month, two, two months, and three, six months or longer, and (5) over 85, one (5%), lasting six months (fig 7) Thus the incidence of this complication increases with increasing age, particularly when the population distribution is taken into account

The ophthalmic division of the fifth cranial nerve was *involved in 36 (17 5%) of the 206 patients in this* study Complications such as iritis, conjunctivitis, keratitis, and extraocular muscle paralysis occurred in 12 patients (5 8%) It can be seen that complications associated with this particular segmental distribution were more common than complications arising from any other one group—33 3% in a total of 36 cases The most common ocular manifestation was conjunctivitis, occurring in 7 (19 4%) out of 12 of the 36 patients with ophthalmic herpes zoster Keratitis with or without ulcer occurred in an additional three patients (8 4%), while iritis and extraocular muscular paralysis occurred in one patient each (2 8%) The paralysis in the 48-year-old patient with extraocular muscular paralysis cleared within four months Neuralgia occurred in three of these patients, aged 65, 72, and 78 Ocular complications did not appear to be related to the aging process There was 1 (8 3%) of the 12 patients with such complications *in the 20-to-29-year age group and* there were 2 (16 6%) in the 30 to 39-year age group, 4 (33 3%) in the 40-to-49-year age group, 3 (25 0%) in the 50-to-59-year age group, and 2 (16 6%) in the over-60 year age group

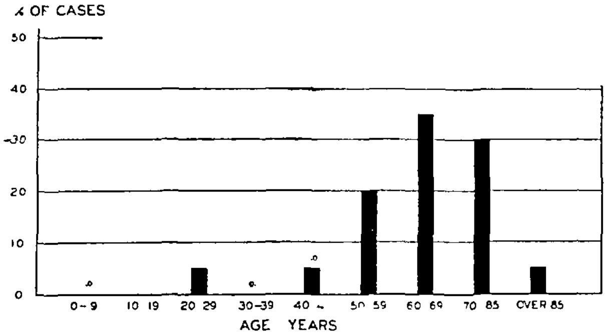

Fig 7—Distribution percentagewise, in various age groups of 20 cases of postherpetic neuralgia

A superficial type of gangrene occurred in two patients, aged 60, or 1% of the total 206 patients studied There was one case of meningoencephalitis in a 3½-year-old child, whose cerebrospinal fluid showed 376 white blood cells, with 40% polymorphonuclear cells and 60% lymphocytes, and normal chloride, protein, and sugar values Electron microscopy of the spinal fluid did not disclose any elementary bodies Another patient, aged 52, with geniculate ganglion involvement had a normal cerebrospinal fluid examination *Three patients had corneal ulcers*

Summary

In order to determine the natural history of herpes zoster infection, 206 unselected cases of the disease were analyzed From the analysis of these cases, we conclude that the following facts are significant Age is an important factor, influencing the frequency of the infection, distribution of lesions, severity of cutaneous reaction, and incidence of postherpetic neuralgia Ocular complications do not appear to be related to the aging process Sex, race and season do not influence the incidence of infection A review of the present knowledge of morphology, immunology, and the clinical picture suggests a similarity of the viruses of herpes zoster and chickenpox

Laryngeal Tuberculosis—The occurrence of laryngeal tuberculosis had been of grave prognostic significance prior to the days of antibiotic therapy Now, due to the excellent response to antibiotics, laryngeal tuberculosis is merely a complication although it usually indicates a more severe variety of pulmonary tuberculosis, with breakdown of host resistance The treatment of laryngeal tuberculosis is essentially that of the parent condition, namely, pulmonary tuberculosis Tuberculosis of the larynx responds very well to antibiotic therapy, using a combination of the known effective antituberculosis drugs Healing is brought about in a great majority of cases in about four months but treatment is continued for at least one year and is stopped only if the pulmonary status is satisfactory Effective drugs presently used are streptomycin, dihydro-streptomycin, isoniazid and PAS Apart from voice rest, local therapy is now rarely used—L M Arnold, M D , Management of Tuberculosis of the Larynx, *Journal of the Mount Sinai Hospital,* July-August, 1956

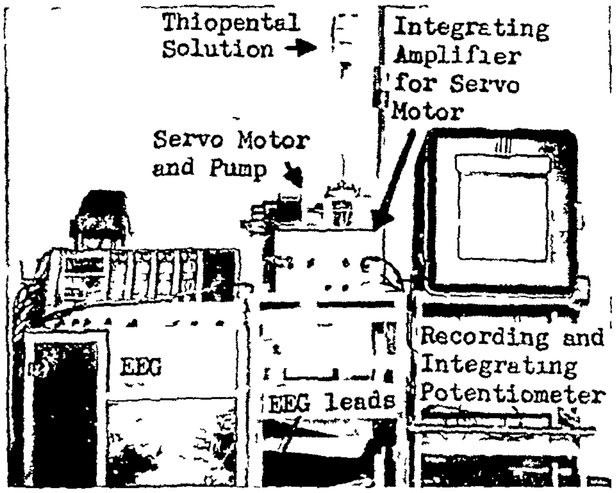
CORTICAL EFFECT OF ALPHAPRODINE AND OF CHLORPROMAZINE DURING THIOPENTAL NARCOSIS

Valentino D B Mazzia, M D, Alan Van Poznak, M D
and
Joseph F Artusio Jr, M D, New York

• *Although the exact mechanism is unknown, the administration of alphaprodine and possibly chlor promazine can produce more satisfactory operating conditions when the patient is under light narcosis with thiopental When the alphaprodine was admin istered, previously restless patients became quiet and stimulation of the skin and venipuncture no longer caused motion or withdrawal, at the same time, a decreased amount of thiopental was needed to pro duce the desired clinical response*

A vast number of surgical procedures have been conducted with the patient under narcosis with thiopental sodium The use of this thiobarbiturate has many clinical advantages, but the drug does lack a true analgesic quality, and the amount of this agent required to provide adequate operating conditions varies widely from patient to patient Prolonged somnolence is an occasional undesirable result

These disadvantages may be somewhat overcome when thiopental is used in conjunction with an analgesic such as alphaprodine (Nisentil) hydrochloride or a thalamic blocking agent such as chlorpromazine, with the result that a form of balanced anesthesia is obtained[1] Laborit and co-workers,[2] Forster and co-workers,[3] Wallis,[4] and Kiersey and co-workers,[5] have stated that the addition of these drugs or similar agents can reduce the thiopental requirement by as much as one-third



Thiopental Solution
Integrating Amplifier for Servo Motor
Servo Motor and Pump
EEG
EEG leads
Recording and Integrating Potentiometer

Fig 1 —Apparatus used for study Frontocentral needle leads connect to terminal board which is connected to electroencephalograph Amplified electrical impulses pass to integrating amplifier, which filters and integrates activity of 24 cps driving the servomotor and pump assembly Thiopental solution from reservoir is delivered at rate appropriate to maintain level of anesthesia in accordance with reference level previously selected on amplifier Thiopental solution is thus delivered according to patient s needs, as determined by cortical electroencephalogram A recording and integrating potentiometer measures the instantaneous flow and amount per time unit of thiopental administered

The purpose of this study is to determine the effect of alphaprodine, levallorphan, and chlorpromazine on the electroencephalographic pattern and on the rat of thiopental administration during thiopental na cosis regulated by a servomotor

Method of Study

Seven patients were included in the study Physic examination revealed no significant central nervou system, cardiovascular, or respiratory disease Surgic procedures were limited to those on the lower e tremities or on the lower part of the abdomen (tabl 1) Four patients received adequate subarachnoi block of the surgical field, adjusted to last at lea throughout the duration of the procedure, with tetr caine hydrochloride–dextrose–epinephrine Ephedrin was included in the procaine solution used for th skin wheal Subarachnoid block was done in order t prevent sensory stimuli from interfering with the e perimental method In three patients, observatio were made prior to surgery and no subarachnoi block was done

Since the servomechanism was not capable of rapi ly inducing anesthesia with a dilute solution of thi pental but could easily maintain any desired level anesthesia, a priming dose of a 2 5% solution of thi pental was given by the anesthesiologist in order t place the patient at the desired level of narcosis shown on the electroencephalogram Frontocentr electroencephalographic needle leads were then i serted, and recordings were made on a Grass electr encephalograph, model III-D An integrating amplifi filtered for activity of 24 cps received the amplifie electrical impulses from the electroencephalograp and activated a servomotor, which in turn drove modified American Optical blood pump This ap paratus delivered a 1 or 2% solution of thiopental a rate to maintain a constant electroencephalograph reading of level 2 narcosis[5] A recording and integra ing potentiometer was included in the circuit to i dicate the instantaneous rate and minute-by-minut volume of thiopental administered

This servomechanism used for the automatic a ministration of an anesthetic agent (fig 1) is simila to the one used for administration of cyclopropan previously described by one of us and co-workers

---

From the Department of Surgery (Anesthesiology), the New York Hospital and Cornell University Medical College

Read before the Section on Anesthesiology at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956

The mechanism has been modified for the administration of thiopental by the substitution of a pump activated by the servomotor for the valve control for cyclopropane and by the substitution of a circuit sensitive to the rate of administration of a solution rather than to the position of a flowmeter valve Ventilation was adequately assisted by the administration of 100% oxygen by a face mask, with closed-circuit carbon dioxide absorption to prevent the development of hypoxia and hypercapnia A stabilization period ranging from 15 minutes to one hour was then permitted until the electroencephalographic pattern and the rate of administration of thiopental became constant

The drugs under investigation were then given Sixty milligrams of alphaprodine was administered intravenously Fifteen minutes later, 1 mg of levallorphan, a narcotic antagonist, was administered intravenously Fifteen minutes later, an intravenous dose of 4 or 5 mg of chlorpromazine was given After 15 minutes of observation, an additional dose of thiopental was given rapidly into a vein other than the one used by the servomechanism and the effect was noted

Results of Study

After a priming dose of thiopental ranging from 250 to 875 mg, a 1 or 2% solution of thiopental was administered by the servomotor to maintain an electroencephalographic reading of level 2 narcosis The administration of an average of 21 3 mg of thiopental per minute was required, with a range of 10 3 to 50 4 mg per minute The general condition of the patients at this time was as follows There was spontaneous respiration, noxious stimulation or venipuncture caused withdrawal flexion reflex, and occasionally there was spontaneous motion Blood pressure and pulse were stable at the levels normal for each patient The results are summarized in tables 1 and 2 Also see figures 2 and 3

Alphaprodine—Alphaprodine, 60 mg given intramuscularly at a rate of 30 mg per second, had no effect on the electroencephalographic pattern or on the rate of thiopental administration However, there were marked clinical changes Previously restless patients became quiet Stimulation of the skin and venipuncture no longer caused motion or withdrawal In three of the patients, apnea resulted and in one, a decrease in respiratory depth

Levallorphan—Levallorphan, 1 mg given intravenously at a rate of 0 5 mg per second had no effect on the electroencephalographic pattern or on the rate of thiopental administration in five patients After receiving levallorphan, two patients who had had apnea resumed spontaneous respiration and one patient with decreased depth of respiration resumed full activity Two doses of 1 mg each failed to restore spontaneous respiration in one patient No other effects of the administration of levallorphan were noted

Chlorpromazine—Chlorpromazine, 4 or 5 mg given intravenously at a rate of 2 to 2 5 mg per second, had no effect on the electroencephalographic pattern or

5	None			None		Preoperative study
6	Apnea no response to venipuncture	2 in 2 doses	Spontaneous respiration	5	None	Preoperative study
7	Apnea	1	None	5	Fall in blood pressure tachycardia	2 days in spite of light narcosis shown by EEG

* 60 mg of alphaprodine was administered to each patient with no effect on the thiopental requirement

† Administration of levallorphan had no effect on thiopental requirements

‡ Administration of chlorpromazine had no effect on thiopental requirements

on the rate of thiopental administration in five patients In four of the five patients tachycardia averaging 34% was noted, and in three of the five patients there was an average fall in blood pressure of 48 mm Hg systolic and 23 mm Hg diastolic After the effect of chlorpromazine was observed for 15 minutes, a dose of thiopental ranging from 100 to 250 mg was administered rapidly through a vein other than the one used by the servomechanism This produced an electroencephalographic pattern characteristic of a deeper level of narcosis and a decrease in the administration of thiopental by the servomotor

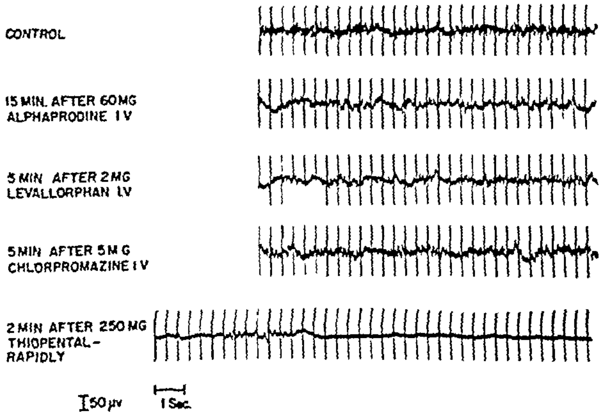

Fig 2 —Effect of alphaprodine levallorphan, chlorpromazine and additional thiopental on electroencephalographic pattern during light anesthesia with thiopental Cortical electroencephalogram is unchanged by administration of first three drugs despite change in clinical condition (see text) Administration of additional thiopental however, causes deeper level of anesthesia as seen on electroencephalogram

Comment

The administration of alphaprodine, levallorphan, and chlorpromazine does not alter the cortical electroencephalographic pattern when the patient is under light narcosis with thiopental, nor does it modify the amount of thiopental required for the servomechanism to maintain an electroencephalographic reading characteristic of light narcosis The administration of alphaprodine and possibly chlorpromazine can produce more satisfactory operating conditions when the patient is under light narcosis with thiopental, but these drugs do not accomplish this goal by the potentiation of the cortical-depressant action of thiopental Rather, these drugs act at sites as yet unknown

The validity of the servomechanism should be discussed at this point That the servomechanism is valid for administering thiopental has been shown by the fact that the manual administration of an extra dose of thiopental produces a deeper level of narcosis, with a corresponding change in electroencephalographic pattern and a lessening of the amount of thiopental administered However, if a drug is given that produces apparently deeper narcosis without affecting the cortical electroencephalogram, the servomechanism will not be sensitive to this change and will continue to administer thiopental in terms of the requirements established by the findings on cortical electroencephalogram In view of the work of Magoun[7] and others on the importance of the ascending reticular system in anesthesia, the need for electroencephalographic recording from areas other than the cortex is submitted for consideration

The servomechanism is a feedback loop that attempts to reach equilibrium by meeting those changes in the patient's condition that it is able to detect Systems have been constructed to measure and record all of the modalities observed by the anesthesiologist Given a sufficiently complex computer that is able to interpret the meaning of these findings, the maintenance of an adequate level of clinical anesthesia by a multichannel servomechanism is not impossible However, the number and type of observations and interpretations that such a machine can make will be limited by its construction In a situation that calls for new powers of observation or interpretation, the servomechanism would be inadequate It is this last limitation that probably explains the apparent discrepancy in our finding of altered operating conditions without a change being apparent in the cortical electroencephalogram

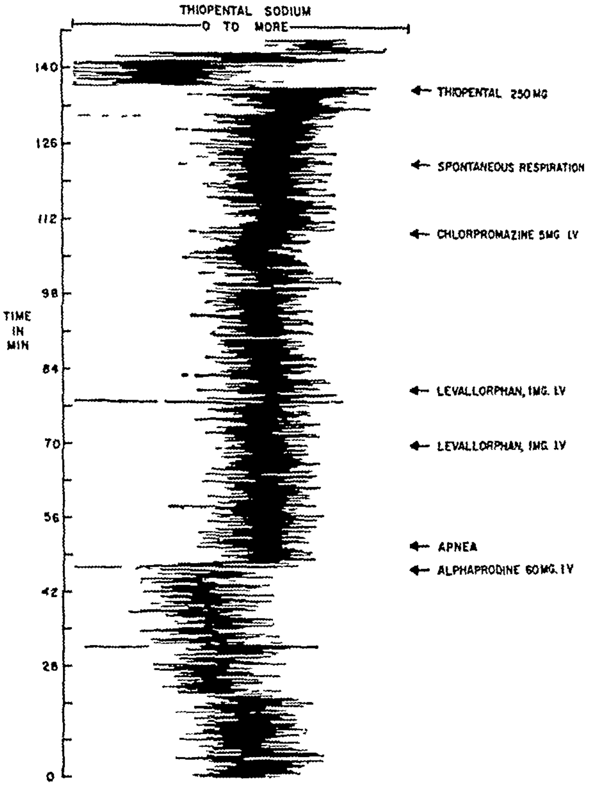

Fig 3 —Effect of alphaprodine, levallorphan, chlorpromazine, and additional thiopental on rate of administration of thiopental regulated by servomotor First three drugs do not alter rate of administration of thiopental, despite changes in clinical condition of patient Administration of additional thiopental, however depresses cortical electroencephalogram and, thereby, decreases amount of thiopental given by servomechanism

That the requirement for thiopental during surgery can be reduced by the additional administration of alphaprodine is clear, for, in the series of Foldes and associates[8] of 852 patients, satisfactory operating conditions were obtained in 92 patients with the administration of alphaprodine and levallorphan alone, without thiopental

Conclusions

The administration of alphaprodine, levallorphan, and chlorpromazine does not alter the electroencephalographic response during light thiopental narcosis, nor does it decrease the dosage of thiopental required to maintain a constant electroencephalographic pattern showing light narcosis The administration of alphaprodine and possibly chlorpromazine does produce clinical changes that result in more satisfactory operating conditions and, thereby, decreases the thiopental requirement by mechanisms that are not yet elucidated

HOSPITAL HOUSE STAFFS, 1950-1955

Harold S Diehl, M D, Minneapolis, Edwin L Crosby, M D, Chicago
and
Paul K Kaetzel, A B, Washington, D C

- *More than three fifths of the physicians who complete internships today continue specialty training without interruption The number of internships and residencies offered in approved programs is nearly three times what it was before World War II For 1955 1956, 8,780 interns and 21,213 residents were reported in training in the hospitals studied Of the 8,780 interns, 2,300 were aliens Analysis of the figures showed that the number of native interns had increased during the period studied but that the number of alien interns had increased much faster Even so, 17% of the internships as well as 19% of the residencies were unfilled The increase in the number of physicians taking specialty training since 1952 has been accounted for entirely by aliens There has been a decrease in the number of residents specializing in tuberculosis and a striking increase in the number specializing in anesthesiology The facts obtained by the Health Resources Advisory Committee afford a basis for consideration of many problems of the staffing of hospitals and the mobilization of medical resources*

One of the significant developments in the training of physicians has been the expansion of hospital residency programs Today, more than three-fifths of the physicians who complete internships continue specialty training without interruption Others, upon discharge from military service, return to hospitals to begin or complete residencies

Through these programs for graduate medical education, physicians have an opportunity to acquire and develop specialized knowledge and skills in diagnosis and treatment before entering medical practice Incidental to this training, such physicians provide hospitals with needed staff and make significant contributions to the provision of medical care

In recent years the demand for hospital services has increased tremendously Between 1950 and 1955 hospital admissions rose from about 18 million to 21 million and the average daily hospital census increased from 1,250,000 to almost 1,400,000 Increase of population (due primarily to increases in both birth rates and longevity), a rising economic level, development of prepayment plans, and increasing awareness of health needs and medical advances have all contributed to the increased demand

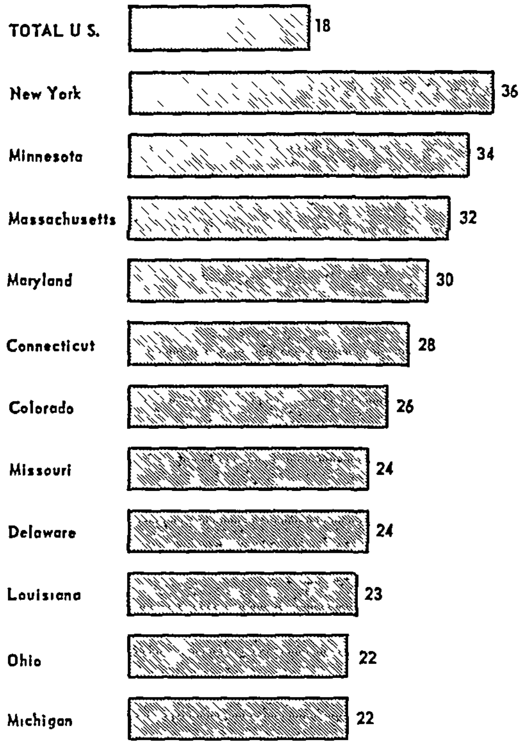
In 1955-1956, more than 38,000 internships and residencies were offered in approved programs at 1,400 hospitals This compares to 30,000 positions offered by

---

Member, Health Resources Advisory Committee, and Dean of Medical Sciences, University of Minnesota (Dr Diehl), Member, Health Resources Advisory Committee, and Executive Director, American Hospital Association (Dr Crosby), and Member, Health Resources Advisory Committee Staff, Office of Defense Mobilization (Mr Kaetzel)

1 100 hospitals in 1950 and only 13,000 prior to World War II As shown in table 1, a considerable number of these positions have not been filled, although the percentage unfilled has been decreasing over the past three years In 1950, 32% of the internships and 25% of the residencies were unfilled The comparable figures for 1955 were 17 and 19% respectively

The Korean war created an immediate and urgent need for additional medical and dental officers for the armed forces In order to provide them, Congress passed Public Law 779, the "doctor-draft' act Among other provisions, this law specified the order of call, by designating four different priority groups Priorities 1 and 2 consisted of physicians and dentists who were permitted to continue their education during World War II, priority 3 included those who had neither deferment nor military service, and priority 4 consisted of veterans



States with highest ratios of hospital house staffs per 100,000 civilian population, 1955

Since 1950, when the doctor-draft law become effective, the Health Resources Advisory Committee of the Office of Defense Mobilization has conducted yearly surveys of interns and residents in approved programs at hospitals (The Health Resources Advisory Committee also serves as the National Advisory Committee to the Selective Service System) Hospitals operated by the Department of Defense and the Public Health Service were excluded from these surveys The purpose of these surveys has been to show (1) normal or existing staffing levels which could be used as bench marks in mobilization planning and (2) the extent of losses due to military withdrawals under the "doctor-draft' law Participation by hospitals having approved training programs was 97% or higher in each of the six survey years

House Staffs, 1955-1956

For 1955-1956, 8,780 interns and 21,213 residents were reported in training at hospitals in 45 states, the District of Columbia, the Canal Zone, Hawaii, and Puerto Rico (Here and elsewhere in this report, the term 'residents" includes second-year and third-year interns, residents, and fellows The term "interns' includes only first-year interns) Over one-half of these interns and residents were in six states—New York, Pennsylvania, California, Ohio, Illinois, and Massachusetts New York and Massachusetts ranked first and third, respectively, in number of house staff per 100,000 civilian population (see figure)

* Excluding Department of Defense and Public Health Service hospitals

Five Year Trends

Total Number of Interns and Residents —In 1950, before the mobilization of physicians got under way, hospitals had staffs of more than 24,000 interns and residents In 1951 and in 1952, in spite of extensive withdrawals under the "doctor-draft" law, hospital house staffs numbered about 23,000, a level only 5% below the 1950 total In each of the three subsequent years (1953-1955), hospital house-staff totals showed an increase over the 1950 level—6% in 1953, 15% in 1954, and 23% in 1955 (table 2)

Over the five-year period, there was an annual increase in the number of interns, with the 1955 total 40% above the 1950 figure On the other hand, the number of residents in 1951 and 1952 was about 2,000 less than in 1950 In 1953, the number of residents approximated the 1950 total, in 1954, there were 10% more, and in 1955, 17% more than in 1950

These increases are reflections of increases both in numbers of medical school graduates and in numbers of alien physicians taking training in this country In addition, for the past several years, the armed forces have been returning physicians to civilian life at about the same rate as they have been withdrawing from it

Citizenship Status—As pointed out earlier, comparison of 1955-1956 data with those of 1950-1951 shows an over-all increase of 23% in house-staff members When the data for citizens and aliens are viewed separately, a somewhat different picture appears (table 3) Over the five-year period the citizen group showed a slight (1%) decrease—22,120 as compared to 22,370—while the alien group increased 280%, from 2,072 to 7,873

Over this five-year period the total number of interns increased from 6,237 to 8,780, or 40% The citizen portion of the increase, however, was only about 1,000, or 18%, while the alien portion increased from 700 to 2,300, or 218% The total number of residents increased from 18,205 to 21,213, or 16% since 1950, with all of the increase accounted for by the alien group, which increased more than 300% In fact, between 1950 and 1952, the number of citizens taking residencies dropped from 16,855 to 13,196—a 22% decrease This was due to military withdrawals from the age group which normally fills residencies In 1953, numbers of citizen residents in training began to increase, and, by 1955, although the number was 7% below the 1950 level, it was 18% above the five-year low in 1952

* Excluding Department of Defense and Public Health Service Hospitals

By 1955, more than 900 of the 1,400 hospitals with approved graduate medical education programs had one or more aliens in training, with about one-half of the aliens concentrated in four states—New York, Illinois, Ohio, and New Jersey States which reported high proportions of alien house staffs were New Jersey, 68 0%, West Virginia, 60 5%, Arizona, 49 4%, Illinois, 37 1%, Maryland, 36 2%, Rhode Island, 34 9%, Ohio 34 8%, and New York, 34 7% (table 4)

Priority Distribution—The doctor-draft law specified the order of call to military service of medical and dental personnel by designating four priority groups The proportion of house-staff members reported in priorities 1 and 2 decreased from 24% in 1950 to an almost negligible number in 1955

The number of priority 3 physicians in training increased from about 3,000 in 1950 to about 4,200 in 1955 This is a reflection of the rising proportion of nonveteran graduates who have been deferred for the completion of their education and an internship Priority 3 registrants comprised 18% of the interns and 10% of the residents in 1950, as compared to 32% of the interns and 7% of the residents in 1955

House staffs in 1950 through 1953 were made up increasingly of priority 4 physicians These men were veterans of World War II or Korea By 1953, priority 4 physicians accounted for more than one-half of all physicians in training Beginning with 1954, the proportion of house-staff members who were priority 4 dropped, and, by 1955, although there were about 2,000 more in training than in 1950, they comprised about the same proportion of total staff—40%

Hospital Specialty Service—Despite the over-all increase of 16% in the number of residents between 1950 and 1955, there was a decrease of 24% in the number of residents specializing in tuberculosis The number on eye, ear, nose, and throat services showed no change during this five-year period Increases occurred in all of the other specialties, the largest being a 66% increase in anesthesiology Other substantial increases were pathology, 36%, neurology and psychiatry, 34%, general practice, 28%, and radiology, 27% (table 5) Internal medicine, which accounted for 21% of the total residents in 1955, and general surgery, which accounted for 23%, increased 4 and 12%, respectively, between 1950 to 1955

Future Outlook

An increase in the number of citizen interns is anticipated for the years immediately ahead Medical school enrollments are at record levels Since 1951, two new schools have gone into operation and are now graduating students Another school began enrolling students in 1955 and will graduate the first class in 1959 Two other schools, which formerly had two-year programs, are in the process of developing four-year programs and will graduate students by 1957

Since 1952, the increase in the number of physicians taking specialty training has been accounted for entirely by aliens The next few years, however, should bring an increase in the number of citizen residents Even if the proportion of each graduating class that takes residency training remains constant, the increase in the number of medical school graduates will result in an increase in the number of citizens taking residency training

Summary and Conclusions

Hospital house-staff surveys have been conducted annually, since 1950, by the Health Resources Advisory Committee of the Office of Defense Mobilization Some of the important aspects of the analysis of these surveys are as follows 1 Over the five-year period the total number of interns in approved programs in hospitals has increased by 40 8% and the number of residents by 16 5% 2 The number of interns who are United States citizens increased by 1,000, or 18%, and the number who are noncitizens by 1,600, or 218% 3 In 1955, the number of residents who were citizens was 7% below the 1950 level There was a decrease of 22% between 1950 and 1952 as a result of withdrawals to enter military service during the Korean war, but since that time the number has been increasing The number of noncitizen residents increased by 4,200, or more than 300%, during the five-year period 4 About one-half of the noncitizens were concentrated in four states—New York, Illinois, Ohio, and New Jersey 5 The proportion of house-staff members reported in priorities 1 and 2, as designated under the "doctor-draft' act, decreased from 24% in 1950 to an almost negligible number in 1955, priority 3 registrants comprised 18% of the interns and 10% of the residents in 1950, as compared to 32% of the interns and 7% of the residents in 1955, and priority 4 registrants accounted for about the same percentage in 1955 as in 1950—40% 6 During the five-year period there was a decrease of 24% in the number of residents specializing in tuberculosis With the exception of eye, ear, nose, and throat, which showed no change, increases occurred in all of the other specialties, the largest being a 66% increase in anesthesiology

These annual tabulations of hospital house staffs have provided the Health Resources Advisory Committee with data necessary for the successful execution of its responsibilities and provide a potential basis for adjustment of staffing in case of more active mobilization

CLINICAL NOTES

BEDSIDE DETERMINATION OF UREA NITROGEN LEVEL IN SERUM OR PLASMA

Elma C Lile, A B , Mario F Villamil, M D , Mark C Rhees, M S
and
Belding H Scribner, M D , Seattle

A quick, accurate test for determining the serum urea nitrogen level is needed for night and emergency work and for routine office screening Caraway[1] describes a rapid turbidity method for determination of urea nitrogen level with use of xanthydrol We find his method to be only semiquantitive, it is able to determine whether the urea nitrogen level is normal or above normal but does not measure satisfactorily the degree of elevation Also, the timing is extremely critical The urea nitrogen test described here is performed on a drop of serum or plasma and is accurate enough for routine clinical needs over the range of 4 to 300 mg per 100 cc It uses a minimum of equipment and stable reagents and is a simple, two-minute test

Principle of Method

The method proposed here is a modification of the method of Van Slyke and Cope[2] One drop of glycerin (glycerol) urease extract (Harleco) is added directly to one drop of serum to hydrolyze the urea to ammonia The hydrolysis is complete within one minute at room temperature The mixture is then diluted with isotonic sodium chloride solution and Nessler's reagent is added to produce color The depth of this color, and hence the urea nitrogen concentration, is determined by comparison with color standards made by Nesslerizing solutions of ammonium sulfate A set of permanent color standards can also be used in the 0-30 mg per 100 cc range, and this makes the procedure a little faster when it is used as a screening test It should be noted that the color is developed in the presence of plasma proteins, which eliminates the necessity for preparing a protein-free filtrate

Equipment

The equipment includes (1) two bottles—one 2-oz plastic bottle for Nessler s reagent and one ½-oz bottle for glycerin urease solution, (2) three droppers—one to deliver the sample (select a standard medicine dropper with an average-size tip, if in doubt check delivery, which, when the dropper is held vertically, should be about 0 4 cc per 10 drops), one for the urease bottle, and one for the Nessler s reagent that delivers 0 7 to 1 0 cc per delivery, (3) four test tubes—Pyrex culture tubes 13 by 100 mm (Corning 9820) to be calibrated by scratching a mark at 3 cc , (4) a standard 1-cc tuberculin syringe for measuring the standard ammonium sulfate solution (measurement is facilitated if the barrel of a 20-gauge hypodermic needle is cut away from its hub, filed to reopen the lumen, and cemented into the tip of the syringe), and (5) permanent color standards Permanent color standards are not essential but can be used for determinations under 30 mg per 100 cc and have colors representing urea nitrogen concentration of 10, 20, and 30 mg per 100 cc The following two solutions are required to make up these three color standards an aqueous solution of phenolsulfonphthalein containing 40 mg of the water-soluble sodium salt in 1,000 cc and any buffer solution of pH 5 0 ± 0 2 (Use Coleman blue label certified buffer tablets or make according to instructions in standard textbooks)

The individual color standards are made up by using the proportions of the above reagents given in the table The color standards should be sealed in

---

From the Veterans Administration Hospital and the Department of Medicine, University of Washington School of Medicine ampuls made from 13 by 100 mm Pyrex culture tubes If the ampuls are boiled for one-half hour after sealing, the colors will remain stable indefinitely

This equipment can be conveniently combined into a small portable kit or included in a larger kit that contains bedside tests for chloride,[3] bicarbonate,[4] and sodium [5]

Reagents

The four reagents used are as follows

1 Glycerin urease extract This appears to be stable indefinitely at room temperature However, it is recommended that the stock bottle be stored in the refrigerator and the supply in the kit be renewed every four to six months

2 Nessler's reagent [6] For Nessler's reagent add 45 5 Gm of mercuric iodide and 34 9 Gm of potassium iodide to a 1-liter volumetric flask and dissolve in 500 cc of distilled water Add slowly to this mixture 200 cc of 10 *N* potassium hydroxide (or an equivalent amount of another concentration) Dilute to 1 liter Protect this reagent from atmospheric carbon dioxide If the reagent is clear, it can be used immediately If there is any turbidity, this can be reduced by storing the reagent in the dark for about two months A small supply of Nesslers reagent is kept in a plastic bottle in the kit Keep the dropper out of the bottle in the kit or the rubber bulb will react with the reagent

Preparation of Color Standards by Placing Indicated Amount of Phenolsulfonphthalein in 100 Cc Volumetric Flask and Diluting to 100 Cc with Buffer

Standard Mg /100 Cc	Phenolsulfonphthalein Cc	pH 5 0 Buffer Cc
10	7 7	92 3
20	12 5	87 5
30	22 7	77 3

3 Standard ammonium sulfate solution This contains 188 6 mg of ammonium sulfate per liter of approximately 0 1 *N* sulfuric acid

4 Isotonic solution of sodium chloride (9 Gm per liter) This is used to dilute samples of serum or plasma and is conveniently dispensed in a small plastic wash bottle

Procedure

The basic procedure is as follows (test tubes must be rinsed free of Nessler's reagent)

1 Measure 0 04 cc (1 drop) of serum or plasma into one of the 13 by 100 mm Pyrex culture tubes This measurement can be accomplished in one of two ways For most clinical needs measurement with a dropper is sufficiently accurate Deliver one drop from the sample dropper described above, being sure that the drop strikes the bottom of the tube If the drop runs down the sides a low result will be obtained The second method is to use an appropriate volume of any convenient dilution of serum in isotonic sodium chloride solution, for example, 1 cc of a 1 25 dilution It is convenient to use a tuberculin syringe to measure the sample and make the dilution in a graduated centrifuge tube

2 Add 1 drop of glycerin urease extract

3 Shake or tap the tube so that all of the sample is completely mixed with the glycerin urease

4 Wait one minute

5 If permanent color standards are not available, prepare color standards in the expected range as follows Place 0 04 cc or 1 drop of serum in each of the 13 by 100 mm Pyrex tubes to be used as a color standard (In addition to the ammonium sulfate, each standard tube contains approximately the same amount of serum as the unknown tube This is essential, since the protein modifies the final color developed when Nessler's reagent is added) Add the appropriate ammonium sulfate with the tuberculin syringe Each 0 01-cc division on the syringe equals 1 mg per 100 cc Thus, to make a 20 mg per 100 cc standard, 0 2 cc of ammonium sulfate would be added to the tube

6 Dilute unknown and standard tubes to the 3 cc mark with isotonic sodium chloride solution

7 Add 1 dropperful of Nesslers reagent (0 7-1 0 cc) to each tube Since the color depends to some extent on the technique of adding the Nesslers reagent, the following standardized technique of addition is recommended Fill the dropper by means of a complete compression of the dropper bulb so that a relatively constant amount of reagent will be delivered Point the tip down the side of the 13 by 100 mm tube and deliver all the Nessler's reagent with one strong squirt that effects instant and complete mixing without producing bubbles

8 If the sample remains clear upon addition of Nessler's reagent, compare with the color standards to determine the concentration of urea nitrogen If the sample clouds, proceed immediately to the technique for high urea nitrogen levels (see below) If the sample color falls outside the range of the color standards, repeat the entire procedure, making up standards in the appropriate range Also remake the sample, as it will darken on standing more than a few minutes If a result of less than 10 mg per 100 cc is obtained, the test tube is probably contaminated with Nesslers reagent from the previous test and this has inactivated the urease

Following is the technique for high urea nitrogen levels

1 The sample size for this technique is 0 008 cc of serum or plasma This can be measured in one of two ways, depending on convenience and the accuracy desired The first method is to place 1 drop of serum measured with a dropper in a small test tube Rinse the dropper and add 4 drops of isotonic sodium chloride solution mixed One drop of this dilution will contain about 0 008 cc of original sample Since the color comparisons are quite accurate with elevated urea nitrogen levels, sample measurement with a dropper introduces a significant error Hence, if greater than ± 15% accuracy is desired, the second method of sample measurement should be used For this, use an appropriate volume of any convenient dilution of serum in isotonic sodium chloride solution For example, if a 1 25 dilution was previously prepared for the first part of the test, 0 2 cc of this could be used, which is equivalent to 0 008 cc of original sample

2 Measure the equivalent of 0 008 cc of original sample in each of 4 Pyrex test tubes (13 by 100 mm) that have been calibrated to 3 cc

3 Add 1 drop of glycerin urease to one of the four test tubes This becomes the unknown Wait one minute

4 Using the tuberculin syringe, add ammonium sulfate solution to each of the other test tubes to make standards in the range expected Usually one would make a 100, 150, and 200 mg per 100 cc standards It requires 0 2 cc of the standard ammonium sulfate for each 100 mg per 100 cc

5 Dilute with isotonic sodium chloride solution all four tubes to approximately the 3 cc mark, though the final volume need not be exact

6 Add 0 7 to 1 0 cc of Nesslers reagent, using the technique described above It is important that the same technique be used on all tubes

7 Wait one minute for full color development, and then compare the unknown with the standards by looking lengthwise down through the four tubes toward a white surface

8 Estimate the urea nitrogen level from this comparison

9 If the unkown falls outside the range of the standards, repeat the entire procedure, making appropriate standards Do not use the original unknown, as it may darken on standing more than a few minutes

Result

One hundred thirty samples were analyzed for urea nitrogen by the bedside method, and the results were compared with those obtained by the method of Van Slyke and Cope [2] with use of a Somogyi filtrate In the range of 4 to 30 mg per 100 cc of urea nitrogen the standard deviation on 95 samples was ± 3 0 mg per 100 cc, with a maximum deviation of 7 0 mg In the critical range of 18 to 22 mg per 100 cc the standard deviation on 22 samples was ± 2 1 mg per 100 cc, with a maximum deviation of 2 5 mg In the range of 30 to 100 mg per 100 cc the standard deviation on 22 samples was ± 4 5 mg, with a maximum deviation of 9 0 mg

The technique for high urea nitrogen levels, using accurately measured samples (rather than a dropper), gave the following results The reproducibility on duplicate determination was at least ± 3% When the results on 18 samples in the range of 100 to 300 mg per 100 cc were compared with those obtained by the method of Van Slyke and Cope [2] the standard deviation was ± 4 3 mg per 100 cc and the maximum deviation ± 15 mg

Sources of Error

Turbidity—When the sample size is 0 04 cc and the urea nitrogen concentration exceeds 100 mg per 100 cc, turbidity will usually develop in both unknown and standard tubes Since this can make comparisons inaccurate, all turbid specimens should be discarded and the test repeated with use of the 0 008-cc sample size and the technique for high urea nitrogen levels Nesslers reagent itself will become turbid on prolonged exposure to air, therefore, keep only a small supply in the kit Renew the supply in the kit if turbidity develops

Contamination—Test tubes should be rinsed thoroughly with water after each determination If any Nesslers reagent remains in the test tube, the mercury in the Nesslers reagent will inactivate the urease and no color will develop with the addition of Nessler's reagent

Jaundice and Hemolysis—Moderate to severe icterus and severe hemolysis make color comparison with the permanent color standards difficult and uncertain However, since ammonium sulfate color standards made up with the icteric serum also contain the interfering color, comparison is not a problem With icteric or hemolyzed serums, therefore, it is best to always make up ammonium sulfate color standards

Urease Deterioration—Urease may deteriorate after prolonged storage at room temperature, forming ammonia-containing products To test for deterioration, place 2 drops of urease in a 13 by 100 mm test tube and dilute to 3 cc Add Nesslers reagent Deterioration is indicated by the appearance within 30 seconds of color approaching the depth of the 10 mg per 100 cc standard

Checking Permanent Color Standards

The accuracy of the permanent color standards may be checked by comparing them to ammonium sulfate color standards prepared as described above

Clinical Applications

The simplicity of this technique for accurate measurement of urea nitrogen should make it possible to perform the test as a routine screening procedure on all patients from whom blood is drawn This test should also prove of value in the emergency evaluation of critically ill patients The technique for high urea nitrogen levels has a remarkable degree of reproducibility for such a simple test This makes it possible to detect small day-to-day changes in the degree of elevation of the urea nitrogen level in uremic patients Such information is of particular value in the management of patients with acute uremia

Summary

A simple, two-minute quantitative test for the direct determination of urea nitrogen level on serum or plasma is accurate enough for routine clinical use over the entire range of concentrations encountered in patients

4435 Beacon Ave (8) (Dr Scribner)

This study was supported in part by grants from Abbott Laboratories the American Heart Association, and the Schweppe Foundation

A complete test kit for this procedure, as well as separate items of equipment, including sets of permanent color standards, are manufactured by Rochester Products Co, Rochester Minn

COUNCIL ON DRUGS

Formerly the Council on Pharmacy and Chemistry

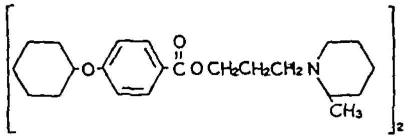
NEW AND NONOFFICIAL DRUGS

Formerly New and Nonofficial Remedies

Monographs and supplemental statements on drugs described here and in subsequent editions of New and Nonofficial Drugs are based on the evaluation of available scientific data and reports of investigations. Applicable commercial names for preparations of evaluated drugs are listed at the end of monographs and parenthetically in the text of supplemental statements, additional commercial names of which the Council is informed will be included with subsequently published supplemental statements and annual editions of New and Nonofficial Drugs.

H. D. Kautz, M.D., *Secretary*

Cyclomethycaine Sulfate.—3-(2-Methylpiperidino)-propyl *p*-cyclohexyloxybenzoate sulfate.—The structural formula of cyclomethycaine sulfate may be represented as follows:



Actions and Uses.—Cyclomethycaine sulfate, a topical anesthetic agent, belongs to the benzoic acid group of compounds, but its hydrolysis does not yield *p*-aminobenzoic acid. Hence, the anesthetic properties of the drug are not affected by concomitant sulfonamide therapy. Cyclomethycaine sulfate acts on damaged or diseased skin and on the mucosa of the rectum, vagina, urethra, and urinary bladder. The drug is relatively ineffective on the mucous membranes of the mouth, nose, trachea, bronchi, and eye. It does not penetrate the tympanic membrane and is, therefore, not beneficial in otitis media.

Cyclomethycaine sulfate is an effective topical anesthetic for abrasions and for certain types of surface skin lesions characterized by pain, pruritus, and cutaneous irritability. It also is useful for rectal and vaginal conditions in which pain arises in the mucous membrane or ulcerated fissures. After urethral instillation, the drug produces sufficient anesthesia to permit passage of sounds and cystoscopic examination. Cyclomethycaine has also been used for the relief of pain in burns. However, some experts in this field do not favor the use of topical anesthetics in burns, especially when large areas of the skin are involved, because of the increased hazard of systemic absorption.

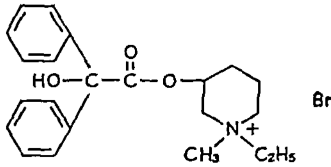
As with all topical anesthetic agents, cyclomethycaine sulfate carries a slight but predictable sensitizing potential when utilized on patients with allergies or in conditions of prolonged use. This fact should be borne in mind, especially when the drug is used in the rectum or vagina, although this potential is less than that with compounds comprising *p*-aminobenzoic acid; use of the drug should be discontinued immediately if manifestations of dermal or mucosal sensitivity occur.

Dosage.—Cyclomethycaine sulfate is applied topically as frequently as necessary to maintain surface anesthesia. For such use, the drug is administered in a suitable dermatological vehicle usually containing from 5 to 10 mg. per gram (0.5 to 1% concentration). For topical anesthesia of the rectum, 10 mg. of the drug may be administered, usually in the form of suppositories. For anesthesia of the urethra prior to urologic instrumentation, a jelly or solution containing 7.5 mg. per cubic centimeter (0.75% concentration) is used. The usual dose for intraurethral instillation is 2 to 10 cc. (15 to 75 mg.) in the male and 1 to 4 cc. (7.5 to 30 mg.) in the female.

Applicable commercial name: Surfacaine.

Eli Lilly and Company cooperated by furnishing scientific data to aid in the evaluation of cyclomethycaine sulfate.

Pipenzolate Methylbromide.—1-Ethyl-3-piperidyl benzilate methylbromide.—The structural formula of pipenzolate methylbromide may be represented as follows:



Actions and Uses.—Pipenzolate methylbromide, a synthetic anticholinergic agent with predominantly peripheral atropine-like effects, is closely related in chemical structure and pharmacological action to piperidolate hydrochloride. It is more potent than the latter agent, however, and produces a gastric antisecretory effect in addition to decreasing gastrointestinal motility. The drug appears to exert a more generalized spasmolysis than does piperidolate, since therapeutic doses usually affect the smooth musculature of the biliary tract also.

The chief clinical use of pipenzolate methylbromide is in the adjunctive treatment of peptic (gastric and duodenal) ulcer. It is no more effective than atropine in relieving hypermotility, however, it does decrease gastric secretion, thereby being somewhat more advantageous than atropine for this purpose. It should be borne in mind that anticholinergic therapy for peptic ulcer should be adjunctive to proper dietary management Pipenzolate also relaxes spasm of the lower gastrointestinal tract and the sphincter of Oddi and may therefore prove useful for the treatment of ileitis, the irritable colon syndrome, and other functional disorders of the gastrointestinal or biliary tracts

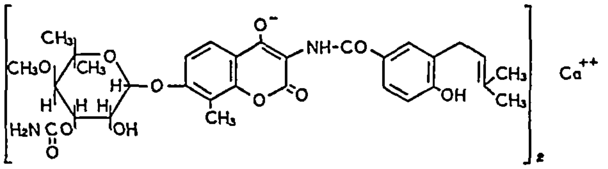
Side effects associated with pipenzolate therapy are chiefly atropine-like in nature but, after therapeutic doses, are less severe and less frequent than with the belladonna alkaloids No serious toxic reactions have been reported, however, the same precautions and contraindications should be observed with pipenzolate methylbromide as with other agents of this class

Dosage —Pipenzolate methylbromide is administered orally The average dose for adults is 5 mg three times daily before meals and 5 to 10 mg at bedtime, however, dosage must be individualized to fit the needs and response of the particular patient

Applicable commercial name Piptal

Lakeside Laboratories, Inc, cooperated by furnishing scientific data to aid in the evaluation of pipenzolate methylbromide

Novobiocin Calcium —The calcium salt of an antibiotic substance produced by fermentation from cultures of Streptomyces niveus —The structural formula of novobiocin calcium may be represented as follows

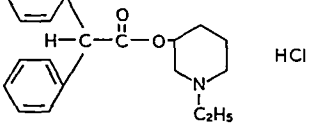


Actions, Uses and Dosage —Novobiocin calcium has the same actions and uses as novobiocin sodium It differs from the latter salt chiefly in being less alkaline and more stable in a liquid form Accordingly, the calcium salt is primarily suited for oral administration in liquid form, especially for pediatric use or for those patients who prefer liquid medication to a solid form of the antibiotic Novobiocin calcium is administered in the same dosage as the sodium salt (See the monograph statement on novobiocin sodium in THE JOURNAL, Feb 23, 1957, page 646)

Applicable commercial name Albamycin Calcium

The Upjohn Company cooperated by furnishing scientific data to aid in the evaluation of novobiocin calcium

Piperidolate Hydrochloride —1-Ethyl-3-piperidyl diphenylacetate hydrochloride —The structural formula of piperidolate hydrochloride may be represented as follows



Actions and Uses —Piperidolate hydrochloride, a synthetic derivative of a piperidol, antagonizes acetylcholine, chiefly at cholinergic nerve endings Except in high doses, it does not block ganglions or inhibit transmission to skeletal muscle Its effects on the central nervous system, on conduction within the heart, or on blood pressure, are minimal The principal pharmacological actions of the drug are referable to inhibition of postganglionic parasympathetic nerve impulses Thus, it may be classified as an anticholinergic agent with predominantly peripheral atropine-like effects The clinical use of piperidolate hydrochloride is based on its ability to decrease motility of smooth muscle There is evidence to indicate a high degree of specificity of the drug for the smooth muscle of the gastrointestinal tract, in therapeutic doses, it does not produce appreciable effects on the musculature of the biliary tract Likewise, the drug has little, if any, effect on gastric secretion After oral administration, demonstrable decreases in gastrointestinal motility are apparent within 10 to 20 minutes This rapid action has been attributed to a local anesthetic effect

Piperidolate hydrochloride has been used for the adjunctive management of functional gastrointestinal disorders characterized by pain, spasm, and hypermotility The spasmolytic effect of the drug is more pronounced on the upper than on the lower portion of the gastrointestinal tract, thus it will inhibit gastroduodenal spasm, pylorospasm, and cardiospasm but is without appreciable effect on spasm of the colon It has been demonstrated to relieve the spasm of the biliary sphincter and has been used clinically in various forms of biliary dyskinesia and other biliary disorders accompanied by spasm, as well as in various types of gastric neurosis and irritability

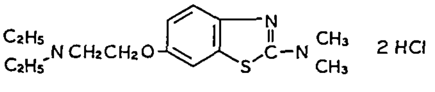
In therapeutic doses, piperidolate hydrochloride appears to be less toxic than atropine or other synthetic anticholinergic agents It produces little xerostomia, dilation of the pupil, tachycardia, constipation, or other atropine-like side-effects No urinary retention or increased intraocular pressure has so far been reported after its administration Owing to its anticholinergic classification, however, the drug should be used with caution in patients with prostatic hypertrophy or glaucoma

Dosage —Piperidolate hydrochloride is administered orally The dosage is governed by the severity of symptoms and the individual response The average dose for adults is 50 mg four times daily, preferably before meals and at bedtime

Applicable commercial name Dactil

Lakeside Laboratories Inc cooperated by furnishing scientific data to aid in the evaluation of piperidolate hydrochloride

Diamthazole Dihydrochloride —6-(2-Diethylaminoethoxy)-2-dimethylaminobenzothiazole dihydrochloride —The structural formula of diamthazole dihydrochloride may be represented as follows



Actions and Uses —Diamthazole dihydrochloride, an antifungal agent, is active in vivo against dermatophytes of the genera Trichophyton and Microsporum and against the monilial organism, Candida albicans Its activity against bacteria and the common nonpathogenic molds is negligible Although the precise mechanism of its antifungal action is imperfectly known, diamthazole has shown fungistatic properties in vitro, it also exerts a mild keratolytic effect and possesses antisporulating properties The drug exhibits good diffusibility on the skin and, when applied in moderate amounts to noninflamed dermal areas, is not absorbed to an appreciable extent into the systemic circulation

Diamthazole dihydrochloride is used clinically for the treatment of superficial fungal infections caused by trichophytons, microsporums, and C albicans Repeated daily use has produced satisfactory results in chronic cases of tinea pedis (athlete's foot) Tinea capitis (ringworm of the scalp) caused by M audouini or M lanosum also responds to its use The latter type of infection, however, often produces an inflammation or kerion and may react adversely to the drug if it is administered during this pyodermic phase Cure rates for tinea capitis after use of diamthazole dihydrochloride range from 50 to 70% Thus, the drug is not as effective as x-ray epilation, which can be expected to effect a cure rate of almost 100% when carried out by skilled personnel The drug may be used in place of x-ray therapy in situations in which adequate facilities and personnel are not available or when total epilation is considered objectionable Diamthazole may also be used for the treatment of tinea cruris, tinea corporis, and tinea versicolor Dermatomycoses such as paronychia and onychomycosis caused by C albicans have likewise been successfully treated with this agent Since the drug is ineffective against bacteria, it may be necessary to administer suitable antibiotic agents along with diamthazole in order to combat concomitant or superimposed pyogenic infections of the skin

In infants and very young children, ataxia, tremors, convulsions, hallucinations, and behavior changes have been reported after use of this drug, but there is more than a suggestion that these effects are due to sucking of fingers or of impregnated skull caps rather than to percutaneous absorption Until more information can be accumulated, diamthazole dihydrochloride is nevertheless contraindicated in children under 2 years of age and should be used in reduced amounts in patients between the ages of 2 and 10 Also because of its possible neurotoxicity, the drug should not be used over extensive areas of the skin for the treatment of superficial fungus infections or tinea versicolor Therapy should not be initiated during the acute or pyodermic phase of any fungus infection, and the drug should be applied on mucous membranes with caution In adults, the only reported signs of toxicity are occasional local irritation and sensitization In the event of these dermal manifestations or any systemic reaction, the use of the drug should be discontinued immediately

Dosage —Diamthazole dihydrochloride is administered topically to infected areas of skin The drug is usually employed in 5% concentration in a suitable dermatological vehicle

For tinea pedis, the acute or pyodermic phase of the infection should be pretreated with a 1 30 solution of aluminum acetate or a 1 10,000 potassium permanganate solution Once the acute phase has subsided, the infected skin is treated once or twice daily with a 5% tincture of diamthazole dihydrochloride, a 5% ointment is applied at night A 5% dusting powder may be sprinkled into shoes and stockings daily during treatment and afterwards to prevent recurrence

For tinea capitis, hair should be clipped from the infected areas and the scalp washed frequently with a bland soap, the drug is then applied as a 5% tincture during the day, and a 5% ointment is rubbed into the infected areas before retiring This daily regimen should be continued for at least three weeks after the first negative Wood's light examination The drug should never be administered during the kerion phase of the infection

For tinea versicolor, a 5% ointment is applied daily to the infected areas after a soap and water scrub Although the infection is often more widespread than is clinically evident, the potential toxicity of the drug precludes its application to the entire body A 5% dusting powder may be used to prevent recurrence or reinfection

A 5% ointment or tincture of diamthazole dihydrochloride is applied twice a day to the involved areas for the treatment of tinea cruris, tinea corporis, paronychia, or onychomycosis

Applicable commercial name Asterol Dihydrochloride

Hoffmann-La Roche Inc cooperated by furnishing scientific data to aid in the evaluation of diamthazole dihydrochloride

Use of Sodium Acetrizoate for Urethrography

The Council has evaluated the usefulness and safety of sodium acetrizoate for retrograde urethrography A preparation of the drug intended for this purpose (Thixokon) is rendered viscous by the addition of a relatively inert, nontoxic thickening agent Nonviscous solutions of sodium acetrizoate (Urokon Sodium) have previously been described in N N R as suitable for intravenous (excretory) urography, retrograde pyelography, intravenous nephrography and angiocardiography, translumbar arteriography, and intraductal cholangiography On the basis of additional evidence, the Council concluded that the thickened solution of sodium acetrizoate is a useful contrast medium for the visualization of the lower urinary tract, including the urethra and its adnexa, the bladder neck, and under certain circumstances, the bladder mucosa Except for occasional irritation to the urethra, the drug has not produced any serious side-effects or toxic reactions It should nevertheless be administered with caution to patients with a definite history of allergy because of the possible occurrence of urethrovascular invasion

For urethrography, 20 to 30 cc of a 50% solution of the viscous material is introduced into the urethra by slow retrograde injection Roentgenographic exposure is made at the end of the injection If the patient has retained urine for two to three hours prior to examination, a satisfactory cystogram is obtained as well After intraurethral injection of the drug, exposures made during micturition also provide adequate voiding urethrograms

The Council voted to amend New and Nonofficial Drugs accordingly to describe this additional use of sodium acetrizoate

Mallinckrodt Chemical Works cooperated by furnishing scientific data to aid in the evaluation of sodium acetrizoate for urethrography

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The following paper was presented at the symposium, "The Relation of Proteins and Amino Acids to Human Nutrition," in Los Angeles, May 21, 1956. The symposium was sponsored by the Council on Foods and Nutrition, with the cooperation of the Los Angeles County Medical Society and the School of Medicine, University of California at Los Angeles. This report is the second of the series. After publication of the sixth and final report, this series will be available in monograph form.

PHILIP L. WHITE, Sc.D., *Secretary*

NITROGEN BALANCE AND THE NUTRITIVE VALUE OF PROTEINS

James B. Allison, Ph.D., New Brunswick, N. J.

Dietary proteins furnish the amino acids for synthesis of tissue proteins and for other special metabolic functions. Synthesis includes the rebuilding of tissue proteins that are being broken down continuously as well as the formation of the new proteins during growth. The process of synthesis is called anabolism, the process of breakdown, catabolism. For anabolism, the amino acids may be pictured as being activated and arranged in their proper places on the surface of an appropriate catalyst, there to be joined together through peptide linkages into a specific long polypeptide chain. This chain may then wind off the catalytic surface into a structure characteristic of the tissue protein formed by that catalyst.

Dynamic State

Some tissue proteins are continuously being broken down and resynthesized, thereby creating a dynamic state in which nitrogen may flow from one tissue to another. This concept was revealed by the work of Whipple [1] and associates and given even more reality by recent experiments involving amino acids tagged with heavy nitrogen or radioisotopes.[2] Amino acids enter a dynamic metabolic pool contributed to by both dietary and tissue proteins, a pool to supply all of the amino acids needed for both catabolic and anabolic reactions.[3] This pool can be described as a summation of protein metabolism in many centers integrated into the dynamic state of the body as a whole. It is assumed that each center, at the cellular level, demands a properly balanced mixture of amino acids for anabolism, the amino acids being derived in part from extracellular sources.[4] The rate of turnover of different proteins, however, varies greatly, some being very labile, some less so, and some so stable that they draw from, but contribute little or nothing to, this metabolic pool. Such a dynamic state can result in the maintenance of one tissue at the expense of another.

The dynamic state of catabolism and anabolism in animals, in whom dietary and tissue amino acids are pictured as forming common metabolic pools, makes difficult the separation of the metabolism of amino acids from food (exogenous) from the metabolism of amino acids from tissues (endogenous). The concept of an endogenous metabolism, however, is valuable for recognizing certain metabolic pathways. Endogenous metabolism, for example, is often identified with the formation and excretion of creatinine, a substance essentially independent of amino acid intake, whereas exogenous metabolism is associated with the excretion of urea, which varies with the quantity and quality of dietary protein. The formation of creatinine, arising from special energy pathways involving creatine, can be correlated best with the functional nuclei of the muscle mass, the origin of urea can be associated with catabolism of amino acids of the metabolic pool. The excretion of creatinine can be increased by the addition of methionine and glycocyamine to the diet, another example of the ultimate effects that diet can exert upon most, if not all, body reactions.

Essential Amino Acids

Twenty-two different amino acids ordinarily are required for synthesis of tissue proteins, and the absence of any one of them could prevent the formation of the polypeptide. The body can synthesize and mobilize the majority of these amino acids from dietary sources, but the classic studies of Rose [5] and his associates have demonstrated that some of the amino acids cannot be synthesized in amounts adequate for metabolic needs. These are called essential, the others nonessential. The essential amino acids must be provided *de novo* every day in the diet in proper amounts and proportions, together with an adequate supply of the nonessential amino acids or some nitrogen compound or compounds to provide the NH_2 groups needed for their synthesis, if protein synthesis and other metabolic functions are to take place normally. Examples of other functions are the formation of the hormones thyroxin or adrenalin from the amino acid tyrosine or the methylation of glycocyamine by amino acid methionine to form creatine, an essential compound in muscle metabolism.

The amount of nitrogen retained in the body is correlated, therefore, with the pattern of essential amino acids provided by the dietary protein. If that pattern is perfect for synthetic purposes, then the

---

From the Bureau of Biological Research, and the Department of Physiology and Biochemistry, Rutgers University.

dietary nitrogen fed, if not given in excess of synthetic needs, would be used in its entirety to build body protein Such a pattern of essential amino acids is approached in egg white (table 1) The reference pattern of essential amino acids for growth in rats and dogs, listed in the first line of the table, was estimated from experiments on the requirements for growth and repletion of soft tissues in animals

The reference pattern is calculated to simulate a dietary protein so that it can be compared with those of the food protein sources also listed in table 1 The pattern should not be taken as final but rather as a step toward determining a reference It will vary from species to species and with the physiological state of the animal Some of the essential amino acids recorded for dietary protein sources are in relative excess of values recommended in the reference pattern Experimental data on the effects of amino acid imbalances indicate that, if the excesses are sufficiently great, the nutritive value would be reduced [6] However, the data to be presented in this paper, together with information from the literature,[3] suggest that most of the nutritive values of natural protein sources are limited more by deficiencies in one or more of the essential amino acids than by excesses

Nitrogen balance is, however, the algebraic sum of gains and losses of nitrogen in all the metabol centers throughout the living system It is possibl for the body as a whole to be in positive balance an still lose nitrogen from some tissues A striking example of this summation is the balance that develop in rats with a transplanted sarcoma in which th tumor-bearing body is in positive balance The growing sarcoma, entering the dynamic state of the body draws from, but contributes little to, the welfare o the tissues through a common metabolic pool It i in positive balance, the liver also may be gaining i nitrogen, but the other soft tissues of the body ar often losing labile protein stores [6a]

These labile stores are the cytoplasmic proteins an the blood proteins, particularly plasma albumin, tha rise or fall as the supply of amino acids increases o decreases in the diet When these stores are fille maximally in the adult, catabolic activity is high, an the excretion of urea nitrogen derived from that activity is high A relatively large amount of dietary nitrogen is needed to maintain these full stores Expresse in terms of nitrogen balance, maintenance is established when the nitrogen intake just equals nitroge excretion Under these conditions nitrogen balanc is zero, and the individual is said to be in nitroge equilibrium At equilibrium, the over-all catabolisn of tissue nitrogen is equaled by anabolism If, at an time, the amino acid intake, expressed as nitrogen, i not adequate to maintain these stores, they will b depleted through excess catabolism Under these conditions nitrogen intake will be less than the nitroge excretion so that nitrogen balance will be negative an the body will be losing nitrogen Negative balance therefore, means depletion in the labile protein stores Continued feeding of a diet deficient in amino acid will cause a reduction in catabolic activity, as measure by excretion of urea nitrogen, and a reduction in th amount of nitrogen needed to maintain the individua in nitrogen equilibrium

These labile protein stores provide a mechanisn for the individual to adapt to various protein intakes For example, a person with full stores who require a high nitrogen intake for maintenance but who i placed on a lower nitrogen intake will go into negativ balance, thereby losing body nitrogen The resultan reduction in catabolism eventually brings about nitrogen equilibrium at the lowered intake Conversel an individual with reduced stores who is placed on a diet to produce positive balance will gain in bod nitrogen The increase in catabolic activity at th higher nitrogen intake will then produce equilibrium

TABLE 1 —*Estimated Patterns of Amino Acids for Growth of Soft Tissues and for Maintenance of Nitrogen Equilibrium in Animals Compared with Patterns of Several Food Protein Sources*[*]

[*] From Allison [3] All units in grams per 100 Gm of protein

If the food protein is deficient in one or more of the essential amino acids, tissue protein synthesis will be restricted, and some of the dietary amino acids will enter catabolic pathways, leading to the formation and excretion of nitrogen primarily in the form of urea The pattern of amino acids illustrated by wheat gluten in table 1 is deficient in lysine and in tryptophan for maximum retention for synthetic purposes For that reason, feeding wheat glutens increases the excretion of urinary nitrogen and results in a lower rate of synthesis of tissue proteins than that observed when egg proteins are included in the diet

Nitrogen Balance

The retention of nitrogen in the body is usually expressed as a nitrogen balance (B), which can be defined by the following equation in which I is dietary nitrogen intake, U is urinary nitrogen, and F is fecal nitrogen excreted $B = I - (U + F)$ Neglecting the small loss of nitrogen through the skin in man, if nitrogen intake (I) is greater than the nitrogen excreted in the urine and feces (U + F), then the balance (B) is a positive figure and the body is gaining in nitrogen A positive nitrogen balance means that the over-all anabolism of tissue nitrogen exceeds catabolism Growing individuals would always be in positive balance Similarly, adults should be in positive balance if they are in need of filling the protein stores [7]

Absorbed Nitrogen and Digestibility

The amount of nitrogen retained is accurately expressed as a function of the amount of dietary nitrogen absorbed into the body. Absorbed nitrogen (A) can be estimated according to the following equation in which I is dietary nitrogen intake, F is total fecal nitrogen, and F_m is fecal nitrogen of body origin, $(F - F_m)$ thereby being fecal nitrogen of dietary origin. $A = I - (F - F_m)$. The value of F_m is customarily determined by measuring the excretion of nitrogen while the individual is being fed a protein-free diet. The assumption is that subsequent feeding of nitrogen will not alter this value of F_m. Digestibility (D) can then be calculated as follows: $D = A/I$.

Digestibility is a very important factor in determining the nutritive value of a dietary protein. For example, raw egg has an antitryptic factor that slows up digestion in the small intestine. Ordinarily this factor is inactivated by gastric juice, however, in dogs depleted in protein stores, inactivation does not occur so that digestion, absorption, and retention of raw egg protein are poor. A similar poor digestibility of raw egg protein has been reported in puppies. Cooking the egg denatures the antitryptic factor, thereby improving the digestibility and nutritive value of egg protein in these animals. Proper cooking in the presence of water also improves the digestion and nutritive value of soybean protein, possibly by denaturing similar factors and by altering the protein. As a result, methionine and other amino acids are liberated more rapidly, providing a better over-all pattern for absorption.[8] Overheating, particularly in the absence of water, can also reduce the nutritive value of proteins by destruction of essential amino acids or by tying them up in new chemical linkages not susceptible to enzymatic digestion.

Nitrogen Balance Index

One of the most valuable ways of estimating the nutritive value of absorbed nitrogen is to measure the rate (K) of change of nitrogen balance (ΔB) with respect to absorbed nitrogen (ΔA), the rate being expressed as follows: $\frac{\Delta B}{\Delta A} = K$

The rate (K) called the nitrogen balance index of absorbed nitrogen is a function of the efficiency of retention of nitrogen for anabolism.[9] Nitrogen balance indexes for absorbed nitrogen are illustrated graphically in figure 1, which shows nitrogen balances produced in dogs fed various amounts of different proteins. The series of curves, originating at a negative balance of -4 Gm. per day per square meter of body surface area, present data obtained while feeding various proteins to dogs with full protein stores. Since the tissue stores are full, catabolic activity is high in these animals. The amount of nitrogen needed to maintain nitrogen equilibrium is relatively high—approximately 4 Gm. per day per square meter of body surface area for egg protein, 5.2 Gm. for beef, 5.5 Gm. for casein, 7.1 Gm. for soybean, and 9.1 Gm. for wheat gluten. In figure 1 the curves are linear throughout the region of negative balance, and the slopes, which are the nitrogen balance indexes, are constant. Under these conditions the catabolism of tissue protein may be constant and independent of nitrogen intakes. If this is true, then the indexes become the fraction of absorbed nitrogen retained in the body of the animal, a fraction defined as the 'biological value' of the dietary proteins. This concept of biological value has been developed in detail by Mitchell,[10] who has contributed much to our understanding of the utilization of dietary nitrogen by the body.

TABLE 2.—*Nitrogen Balance Indexes for Absorbed Nitrogen Determined for Six Proteins**

Subject	Egg Powder	Egg White	Beef	Casein	Peanut Flour	Wheat Gluten

Rat growing	0.87	0.94	0.76	0.69	0.54	0.40

* From Allison.[3]

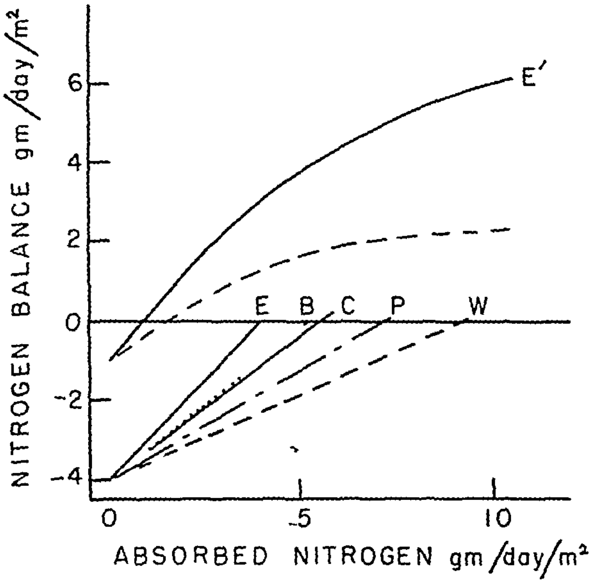

Fig. 1.—Relationship between nitrogen balance and absorbed nitrogen in adult dogs with full protein stores fed the following protein sources: egg, E, beef, B, casein, C, peanut flour, P, and wheat gluten, W. E′ and the dash line represent data obtained while feeding protein-depleted dogs proteins of high and low nutritive value respectively.

The nitrogen balance indexes (biological values) of the six proteins for maintenance in man,[11] dog, and the rat[12] are recorded in table 2. The index for egg protein is close to unity, which can be interpreted to mean that all of the absorbed nitrogen is retained for synthetic purposes, since the pattern of amino acids absorbed is adapted to anabolism. Cystine is not considered an essential amino acid, but, because of the interrelationship between methionine and cystine, the reference pattern for the two are recorded together in table 1. Methionine can be used for the biosynthesis of cystine. Similarly, phenylalanine can be converted into tyrosine, thereby correcting a deficiency of tyrosine if such a deficiency is present in the dietary protein source. Comparing the pattern for egg protein with the reference patterns for growth, the conclusion could be reached that there are excessive amounts of some of the amino acids for protein anabolic needs

Indexes greater than 0 7 represent a protein of relatively high nutritive value The lower index of beef and casein may be associated primarily with a small deficiency in sulfur amino acids needed in relatively large amounts in rats and dogs Adding an optimum amount of methionine to casein increases the index to unity or to slightly above that for egg protein The very low value for wheat gluten is primarily due to a low lysine content Adding an optimum amount of lysine increases the index in dogs to 0 74 the value obtained for casein Obviously, when a protein such as unsupplemented wheat gluten is fed to an adult dog to maintain equilibrium, less than half of the nitrogen fed can be retained for anabolism, and the rest of the amino acids are catabolized, thus increasing the excretion of urea nitrogen The index for wheat gluten in the adult rat, on the other hand, is of the same order of magnitude as the value for casein This high value for maintenance in the rat has been interpreted by Mitchell [13] to mean that this animal can synthesize sufficient lysine to meet the requirement for maintenance, the low index for growth (0 4) would mean that lysine cannot be synthesized adequately for growth Thus the dietary pattern of amino acids needed by the animal may vary with the physiological state The data would indicate, however, that the pattern for synthesis of tissue proteins for growth or repletion of depleted tissues is essentially the same for man, dog, and the rat

* All units in micrograms per gram of protein
† Time after injections days

The amount of dietary protein needed for maintenance in humans fed an ideal pattern of amino acids has been estimated to be approximately 0 5 Gm per day per kilogram of body weight Using this value the requirements for maintenance expressed as grams of protein per day per kilogram of body weight would be egg powder 0 53 egg white, 0 55, beef 0 75, casein, 0 74, peanut flour, 0 90, and wheat gluten 1 2 The value of 1 Gm of protein per day per kilogram often recommended for maintenance in an adult is based on an average diet containing protein varying between peanut flour and casein in nutritive value Also in the recommendation the provision of sufficient nitrogen for building the protein stores adequately is considered However, simply to increase nitrogen intake of a poor protein to meet requirements for equilibrium, which could be done, for example, by feeding 1 2 Gm of wheat gluten per day per kilogram of body weight, does not mean that the physiology of the animal is kept at optimum Feeding a large quantity of a protein of poor pattern for anabolic needs may increase some of the essential amino acids much above requirements thereby creating imbalances that can alter the development of tissues The effects of imbalances, particularly in rats fed a low nitrogen intake have been demonstrated by Elvehjem [6b] Some of the gross effects of amino acid imbalance may actually be the result of competition for passage across cell membranes before anabolism can take place The limitation of protein anabolism by faulty dietary patterns, regardless of nitrogen intake, will be revealed further in the following data

One way to determine the degree of depletion of protein stores in an adult is to determine the degree of positive nitrogen balance that can be produced by a given nitrogen intake, since the greater the depletion the greater the positive balance Most species, including man, do not ordinarily have full stores, hence, they can be put more or less into positive balance until those stores are filled maximally Curve E′ in figure 1 records the data obtained after feeding various amounts of egg protein to a dog badly depleted of protein stores The labile protein stores were reduced in this animal, catabolic activity was low, and very little nitrogen was needed to maintain the depleted state By feeding egg protein, a high positive balance was obtained, showing a great potential for anabolic activity to replenish the depleted stores Repletion by feeding a poor pattern of amino acids is illustrated by the broken curve, such data being obtained while feeding different amounts of protein of low nutritive value No matter how much of this protein was fed, the nitrogen stores could not be filled so rapidly as with egg protein Repletion with a deficient protein such as wheat gluten did not fill the stores so uniformly as did egg protein, resulting in an animal with an imbalance in tissue proteins In general, the nitrogen-balance index for a given pattern of amino acids is higher in the depleted than in the normal animal, a fact which has been interpreted to mean that the reduction in over-all catabolic activity in the depleted state is associated with an increased potential anabolic activity Such an interpretation is supported by the increased retention by various depleted tissues of radioactive sulfur (S^{35}) from methionine labeled with this isotope (table 3)

Growth

The curves in figure 1 have been interpreted to mean that the anabolic efficiency of wheat gluten is much less than that of egg white, no matter how much of the wheat gluten is fed The data showing positive balances were obtained in animals depleted of protein in which the dietary protein was called upon to promote anabolism of repletion The amino acid requirements for repletion are similar to those for growth of new tissues in the young The data in table 4 illustrate the relative protein anabolic efficiencies of egg powder,

TABLE 4 —*Body Weight Gain per Nitrogen Intake, and Nitrogen Balance per Gram of Nitrogen Intake in Beagle Puppies During Fast-Growing Period**

Wheat gluten	5 8	0 18

* From Allison [9]

casein, and wheat gluten for growth[9] These ratios were obtained while feeding puppies sufficient food to obtain approximately the same body weight gain per gram of nitrogen intake in an attempt to produce maximum anabolic activity with a poorer protein such as wheat gluten The data demonstrate that the puppies fed the egg powder gained more nitrogen than those fed casein and that the nitrogen gain in animals fed wheat gluten was very low The animals fed the wheat gluten diet were fat but restricted in development of soft tissues, whereas those fed the egg protein were lean and muscular If the amino acid pattern is too deficient in certain of the essential amino acids, increasing the nitrogen intake of the deficient pattern will not promote protein anabolism to the extent obtained with a better pattern Indeed, feeding larger amounts of the deficient pattern produces an imbalance between fat and lean body mass, resulting in deficiences in some tissue proteins With our present knowledge, it is difficult to establish a dividing line that would make a simple increase in food intake a safe correction for low nutritive value The body, however, does have great adaptive abilities to correct for dietary errors, and possibly a general rule for calculating protein intake would be as follows If the biological value of the dietary protein is greater than 60% of the values obtained for egg or milk proteins the protein intake may be increased to obtain the maximum anabolic activity of the protein This should be done in such a way that the proper balance between caloric and protein intakes is maintained If the biological value of the dietary protein is 60% or less than values obtained for egg or milk proteins, the pattern should be improved by supplementation This supplementation can often be done by proper mixing of various foods or food proteins, helping to correct the amino acid imbalance of the other Supplementation would be particularly important to correct the diet of infants in whom the requirements for essential amino acids per kilogram of body weight may be 10 or more times the requirements for maintenance in the adult

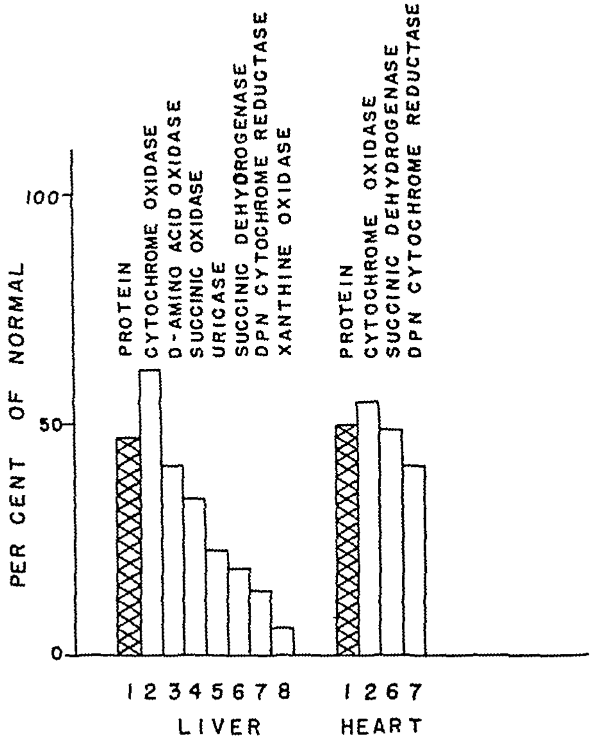

Fig 3 —Enzymatic activities in the liver and heart of protein-depleted rats Data from Allison[14]

Imbalance of Protein Stores

The imbalance in protein stores that develops as a result of protein deficiencies can be illustrated by the shifts that take place during a period of feeding of a low-nitrogen or protein free diet Changes that develop in the circulating plasma proteins of individuals depleted in protein stores are illustrated by the data in figure 2 The plasma albumin is reduced, plasma volume drops, and extracellular fluid increases Total circulating globulins are not decreased greatly and may even increase, particularly in the presence of some debilitating conditions Usually the concentration of plasma proteins decreases, resulting in a hypoproteinemia of depletion Sometimes the fall in plasma volume is so great that, despite the reduction in total circulating proteins, the concentration is still within so-called normal variation

The greatest imbalance associated with depletion is usually observed in the liver Here many, possibly most, of the *labile* protein stores are enzymes, concentrations of which can be described in terms of enzymatic activity as in figure 3[14] Some enzymes, such as xanthine oxidase, are greatly reduced in activity, others, like cytochrome oxidase, may be increased relative to the total liver protein This imbalance in the liver results in altered liver function, which can be detected in many ways One of the most dramatic is to measure the ability of the liver to detoxicate some toxic substance like 2-fluorenamine. This compound is acetylated in the liver of dogs and progressively oxidized, becoming more and more polar until final breakdown into oxidized products. The excretion of a heat-labile, water-soluble derivative has been taken as a measure of the degree of detoxication, the more of this intermediate product excreted, the less complete the detoxication. The effect of dietary casein concentration upon acetylation and detoxication of 2-fluorenamine in dogs is illustrated in table 5.[15] Animals fed the diet free of protein developed the typical imbalance in enzyme systems associated with depletion and, under these conditions, excreted 2.4 mg. of the heat-labile amine. Feeding precisely the amount of casein needed to maintain nitrogen equilibrium in these animals (6.3% casein) reduced the excretion of the amine to 1.3 mg. The diet fed these animals contained vitamin B complex in amounts thought to be adequate for growth. Increasing the pantothenate concentration increased the activity of the liver enzyme involved in acetylation of the amine, leading to an increased excretion of the acetylated product and a reduction in the excretion of the heat-labile intermediate oxidation product. Complete elimination of this intermediate product was obtained after feeding a relatively high-protein diet supplemented with riboflavin, evidently by stimulating the synthesis of liver enzyme systems. Thus effective doses of anesthetics, chemotherapeutic agents, and other medicines may vary greatly with the physiological state of the labile protein stores.

TABLE 5.—*Effect of Dietary Casein Concentration on Acetylation and Detoxication of 2-Fluorenamine in Dogs**

25 + Riboflavin	0.11±0.01	0

* From Allison.[1] All units in milligrams per kilogram of body weight.

Caloric Intake

The proper correlation of caloric with protein intake is important to develop maximum anabolism with the desired proportions of fat to lean body mass. Certain general principles are evolving from various studies between caloric and protein intakes that may be reviewed briefly.[16] There is an optimum caloric intake for maximum protein anabolism, but it varies with protein intake and with the physiological state of the individual. Reducing the calories somewhat below this optimum increases protein catabolism, increasing the quantity of dietary nitrogen needed for maintenance of equilibrium, however, it need not alter the efficiency of utilization of dietary amino acids for anabolism. The data can be interpreted to mean that the individual catabolizes some of the amino acids of the body pool when ingested calories are restricted. A large reduction in calories depletes the protein stores rapidly, but, as the stores decrease, the caloric requirements seem to decrease. The individual also becomes adapted to some extent to the restricted diet.

The data plotted in figure 4 illustrate the response of dogs in various physiological states to caloric restriction. The bars over *A* in this figure illustrate the effect on nitrogen balance of a decrease in caloric intake in dogs fed a constant protein intake. The nitrogen balance decreased in value as the caloric intake was reduced from 3,190 to 2,860 and to 480 calories per day per square meter of body surface area, becoming negative in animals fed the lowest caloric intake. These results illustrate the increased catabolism and loss of nitrogen associated with caloric restriction. Further data suggest that, as the protein stores are increased, catabolic activity increases and caloric requirements are higher. The latter are maximum when the stores are completely filled. Thus, when calories are restricted in an animal with full protein stores, the animal dips deeply into these stores, thereby greatly increasing the excretion of nitrogen. The negative nitrogen balance over *B* in figure 4 was obtained in a dog with full protein stores that was fed 480 calories per day per square meter of body surface area. On the other hand, if the stores are low, catabolic activity is low and the caloric requirements seem to be minimum. Therefore, positive nitrogen balance was produced in a depleted dog (see *C*, fig. 4) fed the same amount of protein and the same low amount of calories fed to dog *B*. Restricted caloric intake for the depleted animal, however, will eventually result in irreversible tissue damage.

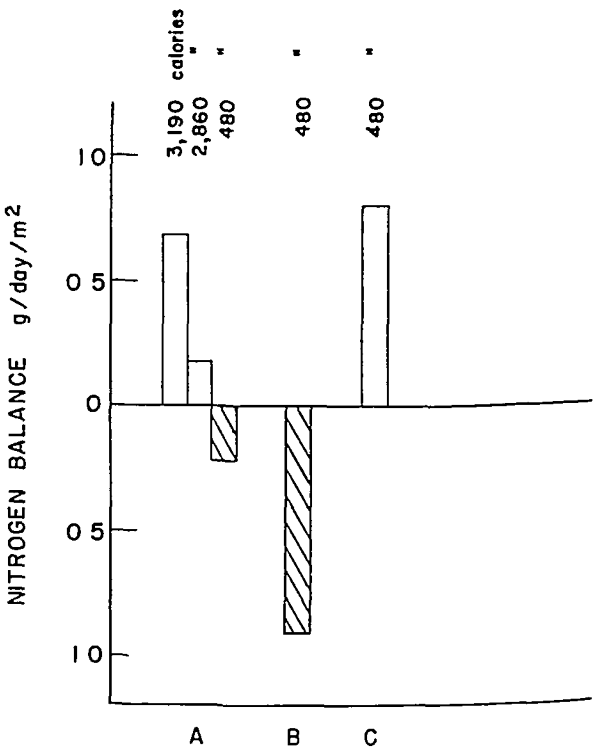

Fig. 4.—Average effect of decrease in caloric intake on nitrogen balance in three normal dogs with constant protein intake (*A*), in a dog with full protein stores (*B*), and in a dog with depleted stores (*C*). Data from Allison.[14]

Summary

This review of protein nutrition and metabolism emphasizes the dynamic state of the labile protein stores These stores are the blood and tissue proteins that increase or decrease in quantity as the dietary nitrogen is raised or lowered respectively The essentiality of certain amino acids in the diet for maximum growth of the tissues is emphasized, giving certain guide lines to help estimate the nutritive value of various dietary protein sources The concept is developed that protein stores are continually being broken down through catabolism, thereby providing energy and amino acids for the metabolic pool This pool may be particularly important to provide energy and essential amino acids during periods of malnutrition associated with sickness, stress, or low food intake

A proper balance between amino acids, furnished by the diet and the body reserves, and all other constituents in the diet would be required for maximum welfare of the body tissues Reduction in caloric intake, for example, increases the utilization of body protein reserves for energy purposes Many tissue proteins are parts of enzyme systems, with their coenzymes of inorganic ions and/or vitamin complexes Thus protein malnutrition may produce symptoms characteristic also of caloric, vitamin, or mineral deficiencies This survey of the metabolic contour map, incomplete as it is, emphasizes the role that all dietary constituents play in the development of these contours The use of amino acids and associated metabolites to alter abnormal contours toward normal is an important and obvious development in nutritional therapy

X-Ray Accuracy —The accuracy of roentgen examinations of the chest was appraised in comparison with autopsy findings in 254 cases with gross chest disease who died within a reasonably short time after filming The objective phase of roentgen interpretation, or rate of demonstrability of intrathoracic lesions, was found to vary proportionately to the diversification of examination techniques from 63 per cent adequacy for frontal projections only through 73 per cent for projections in two or more planes to 100 per cent for fluoroscopy combined with assorted films When all films of unsatisfactory technical quality were excluded, the adequacy rates increased to 68 per cent, 87 5 per cent and 100 per cent respectively The subjective component or personal equation was then investigated and failed to improve with greater adequacy of examinations However, the most objective possible reinterpretation of the original reports disclosed that in 52 cases a correct diagnosis should have been but was not made from the available films The original rate of accuracy of interpretation was 44 per cent but became 65 per cent when correction was made for errors in initial interpretation of adequate examinations Ninety-two per cent of all examinations consisted of frontal projections only, one-fourth of which were bedside films, and the majority of patients were too ill to permit adequate roentgen studies Finally, the effect of the nature and location of 432 lesions upon their demonstrability by various types of examinations was reviewed, confirming that demonstrability varies essentially in proportion to the complexity of filming techniques — J T Littleton III, M D, and J H Feist, M D, The Accuracy of Roentgen Examinations of the Chest, *The Guthrie Clinic Bulletin*, October, 1956

HISTORY-MAKING EVENT IN MEDICAL COMMUNICATION

On the morning of June 5, history will be made in the field of medical communication That day, through arrangements made by Smith, Kline & French Laboratories, two of the world's great medical confraternities—the physicians of the United States and of Great Britain—will be linked for more than an hour via the new underseas cable This 'joint meeting of the American Medical Association, then in annual session in New York, and the Harvey Tercentenary Congress, convened in London on the 300th anniversary of the death of William Harvey, will hear distinguished panelists on both sides of the Atlantic exchange information on cardiac surgery

This is a notable, exciting part of the medical profession's 'person-to-person" program, urged last fall by President Eisenhower And it is fitting that Harvey is the subject of this truly international conference His work is itself an example of the internationalism of science

Circulation of the blood is so basic a part of current medical thought that sometimes we forget the importance of Harvey's contribution unless we recall medical doctrine as it stood at the time of the Renaissance This doctrine held that the liver was the center of circulation and that the heart merely contained air, or blood mixed with air, which left the right side through invisible pores in the ventricular septum Air, passing through the arteries, conveyed "animal spirits" *(animus)* to parts of the body The veins, and the veins alone contained blood The 20th century medical historian Castiglioni has stated that the correction of this concept constituted in the Renaissance "the fulcrum of all physiological knowledge, in fact, one cannot speak of true progress in physiology until the secret of circulation was revealed—a secret that had challenged attention since classical times without having resulted in much progress'

Harvey's challenge was bold and accurate In 1628, he wrote in his monumental "De motu cordis' It is absolutely necessary to conclude that the blood in the animal body is impelled in a circle, and is in a state of ceaseless motion, that this is the act or function which the heart performs by means of its pulse, and that it is the sole and only end of the motion and contraction of the heart"

In arriving at this 'absolutely necessary" conclusion, Harvey had solved various parts of the puzzle of circulation by inductive physical demonstrations But he had as a foundation the work of great names in Renaissance medicine There was Vesalius, a Fleming of German origin, who in 1543 disputed the permeability of the ventricular septum, there was the Spaniard Michael Servetus, who in 1553 stated a rough hypothesis of the pulmonary aeration of the blood, and there was the Italian Fabricus d'Aquapendente, Harvey's own teacher at Padua, who in 1603 elaborately described the valves of the heart To the spread of knowledge in the Renaissance there were no international "curtains", indeed, one Renaissance expert has written of "new reciprocal relations between members of the European group of nations' as a vital characteristic of the Renaissance itself Thus, the work of Vesalius and Servetus was freely available to Harvey—as was the opportunity to study in Italy under Fabricus, perhaps the greatest surgeon of the day

Nor does internationalism end there with the theory of circulation Harvey's book was published on the Continent—in the free city of Frankfurt The entire world of late-Renaissance science—Italy, France, Germany, Scandinavia, the Lowlands and England—entered into the controversy that followed publication of 'De motu cordis' And in the end, the work of many men of different locales—Aselli of Cremona, Jean Pecquet of Dieppe, Malpighi of Bologna—added incontrovertible facts of physiology to Harvey's own findings

It may be fair to say that the lack of nationalism in Renaissance science set the pattern of internationalism that generally characterizes modern science Just as this internationalism long predated current international "curtains,' we believe that it will long outlast them

And perhaps that last statement explains in part why the President's request for a "person-to person" program in the medical sciences is so important in terms of international understanding The many scientific journals, the many international meetings, and free correspondence by men interested in the same search—these provide already-established avenues by which any free nation can prove its goodwill So it is that on June 5, when two medical meetings will be linked, two nations will be linked Not only will science be served, but free men everywhere

TOP FOREIGN FILMS—AN A M A "FIRST"

The estimated 18,000 physicians gathering in New York City for the American Medical Association's Annual Meeting June 3-7 will have a rare opportunity to see some of the finest aspects of foreign medical practice

During the last three and a half days of the convention, 40 outstanding medical motion pictures from abroad will be shown in the Barbizon Plaza hotel This will combine postgraduate education with audio-visual delight, according to representative specialists who have previewed the films during the past five months Subjects range from blastomycosis to volvulus Film-running time varies from 10 to 53 minutes The 15 countries represented reach from Japan to Czechoslovakia, from Brazil to Australia

It will be the first time in the A. M. A.'s 106 annual meetings that American physicians will be able to watch foreign colleagues at work via an international exhibit of medical films. Almost all the scenes are in color, and all will be presented in English. Here is another example of organized medicine recognizing the impact of audiovisual techniques on mass audiences of the profession. It ranks with the previous A. M. A. convention "firsts" of live color telecasts in 1949, scientific exhibits in 1899, and amplified broadcast of human heartbeats.

The A. M. A.'s office of Motion Pictures and Medical Television (under the Council on Scientific Assembly) has arranged the program so that individual film showings will dovetail with section meetings on the same subject. For example, films on pediatrics will be screened prior to section meetings on pediatrics, movies relating to surgery will be shown in the morning, while the section meeting on surgery will take place that same afternoon.

Already, several state medical associations and specialty groups have requested reshowings for their members during the six months that the 16-mm films will remain in this country. They will be loaned on a first-come-first-served basis. The same rule will apply for hospitals, medical schools, and county societies that request the dozen or so motion pictures that the A. M. A. will include in its permanent film library.

There is such great technical interest in these presentations that scores of cinematographers, producers, and audiovisual experts from abroad and many parts of the nation are attending the A. M. A. meeting specifically to study details of photography, animation, and directing. The microscopic photography is described as "superior." One film from Japan, on the structure and function of the middle ear, is characterized by several otologists who have seen it as the finest presentation on hearing concepts ever shown.

This program, presented with the cooperation of Johnson & Johnson, also includes a symposium June 6 on problems in the international exchange of medical motion pictures. There will be *no repeat presentations* of any of the films at the meeting, and seating capacity is limited to 500 per showing. Physicians are therefore urged to plan their attendance in advance by consulting their official program as well as listings in the daily bulletin.

Medical and surgical films speak an international language. Now American doctors, gathered together, will be able for the first time to grasp this world-wide communication in its very essence.

ORGANIZED HOME CARE PROGRAMS

Recently there has been increased attention to the supplying of medical services through what are termed "home care programs." At the very beginning there must be a clear differentiation between home care as has always been provided by the private physician and "organized" home care in which there are coordinated efforts under a central administration that supplies the medical and paramedical services as part of what might be termed a 'team effort.'

The practice of medicine in the United States has always been primarily a home care program in which a physician treated illness in the home where possible, and, at the same time, called upon nursing, social, and rehabilitative services and resources, as he felt they were needed. The family physician has an additional advantage, however, in that, being a personal physician, he also knows which services will actually be utilized, and not merely accepted. For example, when he considers occupational therapy he must judge the receptiveness of the patient. Furthermore, he does not attempt to change nutritional habits without adequate preparation of the patient or those responsible for the care of the patient. In short, his knowledge of the 'whole' patient and the family environment assists him in properly organizing his own team.

Despite the advantages of treatment in a home there were still many patients who required hospitalization. As the shortage of hospital beds increased and as the cost of hospital care rose, especially for prolonged illness, many physicians began selecting certain patients who would not require all the facilities of a hospital and began amplifying their treatment in the home. Paralleling this comprehensive medical care a few organizations developed "home medical services," "hospital extended care programs," and other similarly named services. No matter what they were called, they all served to provide central administration for the coordination of various medical and related services to meet the health needs of the patient and his family.

Because of the expressed interest, not only by the medical profession but by the public as well, the Committee on Indigent Care of the A. M. A. Council on Medical Service conducted a survey designed to obtain basic information on organized home care programs in the United States. Sooner or later, local medical societies will be involved either directly or indirectly with such medical care. It is felt that an understanding of the programs now in operation will be their best guide in evaluating how they will respond if such a program is begun in their own community. The report of the survey prepared by the A. M. A. committee appears on page 298 of this issue.

What started out as primarily a chronic illness program for the indigent has developed into home-hospital services for patients with acute illness and those who are convalescing. Such organized home care programs are promoted by the sponsoring organizations as one of the best means of providing for the medical, social, and rehabilitation needs of certain patients as well as being the total medical care plan for certain groups. No attempt has been made to evaluate the programs now in operation, but it does seem that, as more and more "organized" programs begin to appear, it becomes more and more the responsibility of the practicing physician to assume his share in the planning and administration of such forms of medical care. This should allow the physician, who in the long run directly supplies the predominant service and in essence assumes the responsibility for total medical care, to match his responsibility with authority, and it will at least attempt to prevent the practice of medicine by those who have not graduated *from medical school.*

ORGANIZATION SECTION

MEDICOLEGAL SYMPOSIUMS

More than 1,000 doctors and lawyers from 44 states attended the 1957 American Medical Association medicolegal symposiums presented in Atlanta, Ga, March 15-16, Denver, March 22-23, and Philadelphia, March 29-30 These meetings marked the second time that a series of joint meetings between the medical and legal professions has been sponsored by a national organization The A M A sponsored the first such series in October, 1955, at Chicago, Omaha, and New York City

Dr David B Allman, A M A President-Elect, opened the meetings in Atlanta and Philadelphia Dr George F Lull, A M A Secretary and General Manager, opened the meeting in Denver Local medical society and bar association officials also welcomed the participants at each meeting

Both A M A speakers laid particular emphasis on the need for cooperation between the legal and medical professions, and both noted with satisfaction that the A M A and the American Bar Association national meetings last year featured speeches on medicolegal cooperation from the presidents of the A B A and A M A respectively

Dr Allman outlined four areas in which cooperation between the two professions is needed, i e, preparation and use of doctors who must testify in court, control of narcotics addition and care for addicts, enactment of the Jenkins-Keogh bill, or similar legislation to provide tax deferments for the self-employed on funds to be set aside for retirement purposes, and development of an interprofessional code of understanding for the two professions

Each symposium was devoted to three general topics These were as follows

1 Chemical Tests for Intoxication Under this section the drunken driving problem was analyzed It was generally agreed that the medical and legal professions can do much to reduce highway traffic deaths by encouraging the widespread use of chemical tests in all suspected violations involving drunken driving The importance of chemical intoxication test evidence being accepted by the courts was stressed Experts also testified that use of tests not only would convict the guilty but would absolve the innocent of guilt as well Cases were cited in which death had occurred in persons who were jailed overnight for suspected drunkenness, when actually they were suffering from a head injury or an acute diabetic condition Participants agreed that chemical tests could have prevented these tragedies

2 Trauma and Cancer The second day of each meeting began with a panel discussion on the topic of trauma and cancer The medical panelists reported that a single trauma cannot cause cancer In each case, however, there was at least one attorney who "proved legally that a single trauma may cause cancer Nearly all of the speakers agreed that court decisions are, in most cases, lagging behind accepted medical findings on the relationship of trauma to cancer They also agreed that attorneys, judges, physicians, and law makers should direct their efforts toward correcting the common practice of awarding large settlements in cases where trauma is claimed as a cause of cancer but is not scientifically proved as such

The physicians and attorneys at the three meetings who spoke on this subject were

Atlanta—William F Martin, New York City, attorney, moderator, Theodore J Curphey, M D, Hempstead, N Y, Paul J Grotzinger, M D, Philadelphia, and Hugh G Head Jr and A Walton Nall Atlanta, attorneys

Denver—Alan R Moritz, M D, Cleveland, moderator, A Reynolds Crane, M D, Philadelphia, William F Martin New York City, attorney, and Charles J Traylor, Grand Junction, Colo, attorney

Philadelphia—William F Martin, New York City, attorney moderator, I S Ravdin, M D, Philadelphia, Russell S Fisher, M D, Baltimore, Elwood S Levy, Philadelphia attorney, and Kraft W Eidman, Houston, Texas, attorney

Hugh G Head, who appeared on the Atlanta program, commented on the doctor's responsibility for testifying in court, saying, "it is the duty of the doctor basically to aid and heal the sick and it is a fair inference that it is also the duty of the doctor to be very careful about denying this sick and injured human the prosthetic appliance of the courtroom ’

3 Medical Expert Testimony It was decided in the discussion on medical expert testimony that joint responsibility on the part of the doctor and the lawyer in examining the facts, examining the patient, and preparing or ‘briefing’ testimony beforehand could prevent most cases of miscarried justice in medicolegal suits Lectures and panel discussions pointed out that the most frequent errors by attorneys in this regard are ‘over-cross-examination’ of medical expert witnesses, failure to properly prepare and qualify medical witnesses, and failure to let the doctor know what sort of questions to expect under cross-examination Doctors on the other hand, err most often by exhibiting tendencies to arrogance and hostility under cross examination, by failing to become thoroughly familiar with the medical facts in the case, and by failing to translate the medical history brought out under examination into terms that can be readily understood by the jury

Irving Goldstein of Chicago, attorney, author, educator, and editor, spoke at Atlanta and Philadelphia on Medical Expert Testimony ’ Kenneth W Robinson, veteran trial lawyer, handled this part of the program at Denver

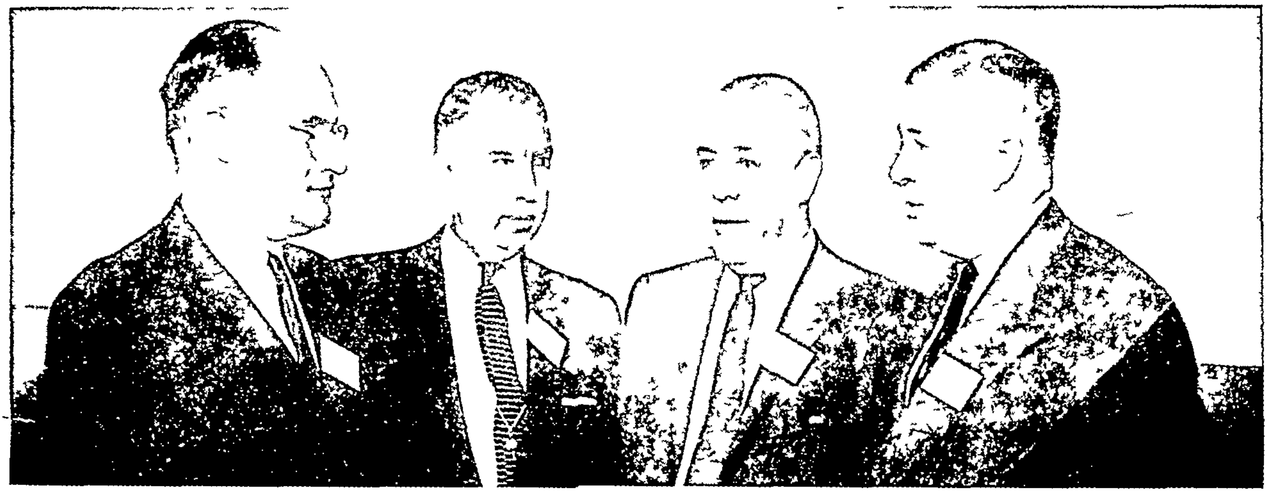
Each symposium ended with a question and answer session between the audience and a panel of medicolegal experts The participants in these panels were as follows

Atlanta—Irving Goldstein, moderator, Edgar F Fincher, M D, Emory University, Georgia, Theodore S Raiford M D, Asheville, N C, and Hamilton Lokey and Edgar A Neely Jr, Atlanta, attorneys

Denver—Kenneth M Wormwood, Denver, attorney, moderator, Charles G Freed, M D, Denver, William M Krigsten, M D, Sioux City, Iowa, Fred J O Connor, Chicago, attorney, and Godfrey Nordmark and Lawrence M Wood, Denver, attorneys

Left Irving Goldstein, Chicago attorney, spoke on "Medical Expert Testimony" at the Atlanta and Philadelphia meetings *Center,* Dr David B Allman, Atlantic City, N J, A M A President Elect, welcomed the groups in Atlanta and Philadelphia and called for a four point program of cooperation between the medical and legal professions *Right,* Dr Herman A Heise, Milwaukee, spoke on "Chemical Tests for Intoxication"

Left, C Joseph Stetler and Capt Robert F Borkenstein before the camera in the mock court trial demonstration A television news feature was sent to 211 U S stations early in March, focusing attention on the symposiums and calling attention to the value of chemical tests for intoxication *Right,* mock trial demonstration showed how to put theory into practice, particularly in the prosecution of drunken driving cases Left to right, Edwin J Holman and Mr Stetler, A M A Law Department, Captain Borkenstein, Indiana State Police, and William J McAuliffe Jr, A M A Law Department, taking test



Opening the symposium at Denver with speeches of welcome were (left to right) Joseph G Hodges, Denver, president, Colorado Bar Association, Dr George R Buck, Denver, president, Colorado State Medical Society, Thomas M Burgess, Colorado Springs, member, Board of Governors, American Bar Association, and Dr George F Lull, Chicago, Secretary General Manager, A M A

Philadelphia—Irving Goldstein, moderator, Robert M Bernstein, Philadelphia, attorney Philip H Strubing, Philadelphia, attorney, Fred J O Connor, Chicago, attorney Abraham M Ornstein, M D, Philadelphia, and Daniel F Featherston, M D Asbury Park, N J

A mock court trial prepared by C Joseph Stetler, Head of the A M A Law Department, was presented on the afternoon of the first day, after a discussion by Dr Herman A Heise of Milwaukee, who spoke at all three meetings on "Chemical Tests for Intoxication—Scientific Background and Public Acceptance" Dr Heise, chairman of the A M A medicolegal subcommittee on chemical tests for intoxication, called attention to the fact that half of the 40,000 traffic fatalities in 1956 resulted from what he termed "alcohol flavored accidents' His remarks elicited favorable editorial comment from a number of newspapers in all parts of the nation Among these was an editorial by Bert Struby, editor of the Macon *Telegraph*, a Georgia newspaper Editor Struby wrote

> His [Dr Heise s] comments turn the spotlight again on a matter which today concerns too few citizens in our state but which in the future, by its own gravity, is going to demand public consideration and action
>
> Speaking at a forum of doctors and lawyers last weekend, Dr Heise pointedly accused alcohol of being the greatest single factor in automobile accidents Yet he said, legal proof of intoxication is extremely difficult without evidence such as that obtained in chemical tests

The mock court trial served to put theory into practice by example With the inexorable drama spelled out in the step-by-step process of law in the courtroom, the fate of one Warren A Drinker, accused of driving while under the influence of alcohol, was sealed

The two-hour demonstration presented a formidable case for the use of breath tests for intoxication The testimony of a medical expert witness, the arresting officer, a police technician who tested the culprit s breath at the time of arrest, and finally the testimony of the defendant himself, all served to illustrate dramatically the points made by Dr Heise The trial proved to be an excellent example of the legal process as it must be coordinated with medical science in order to bring about just verdicts in cases where the establishment of much fact depends upon the skillful presentation of technical scientific data

The actors in the demonstration were as follows

Expert Medical Witness William W Bolton, M D, Associate Director, A M A Bureau of Exhibits, Chicago Police Technician, Capt Robert F Borkenstein, Indiana State Police, Indianapolis, Arresting Officer, Sgt G Herbert Williams, Atlanta Police Department, Georgia, Defendant, George B Larson Assistant Director, A M A Bureau of Exhibits Chicago, Prosecuting Attorney, Edwin J Holman, A M A Law Department, Chicago, Defense Attorney, William J McAuliffe Jr, A M A Law Department, Chicago, and Judge, C Joseph Stetler

The cast of the demonstration trial remained the same for the Denver and Philadelphia symposiums, with the following exceptions

Denver—Arresting Officer, Sgt Thomas O Neill, Denver Police Department, Prosecuting Attorney, Warren E Whyte, A M A Law Department, Chicago, and Defense Attorney, Frank W Barton Secretary, Council on National Defense, A M A, Chicago

Philadelphia—Expert Medical Witness, Dr Herman A Heise, Milwaukee, and Arresting Officer Capt Maurice Pliner, Philadelphia Police Department

"The Medical Witness," a 30-minute motion picture produced by the W S Merrell Company, with the cooperation of the American Medical Association and the American Bar Association, was shown at each symposium The film gives both good and bad examples of courtroom technique It also warns against many of the pitfalls encountered in medicolegal trials

The symposiums were, in effect, a short course designed to bring doctors and lawyers to a better understanding of the responsibilities and interdependence of both professions in the administration of justice C Joseph Stetler, Head of the A M A Law Department, said that another series will be presented in 1959 in the East, the Middle West, and the West

The two following items are from the March, 1957, Bulletin *of the Joint Commission on Accreditation of Hospitals (600 N Rush St, Chicago, Kenneth B Babcock, M D, director) and are reproduced below for the information they contain that will be of interest to many physicians* —Ed

STANDARDS FOR HOSPITAL ACCREDITATION

During 1956, in keeping with the policy of the Joint Commission on Accreditation of Hospitals, the Standards for Hospital Accreditation were under continued study and evaluation This is to insure a dynamic, progressive program established within a framework of solid basic principles with sufficient flexibility to encourage initiative and allow for a maximum of freedom in the implementation of the Standards Any change in the Standards made by the Board of Commissioners as a result of such study is predicated on its effectiveness to safeguard the patient and improve the quality of medical care in hospitals After such study and thoughtful deliberation, the Board of Commissioners, at its meeting in December, 1956, modified Standard II B 4b, concerning attendance at medical staff meetings The old Standard reads as follows

'Active Staff attendance shall average at each meeting at least 75 percent of the active staff who are not excused by the Executive Committee for just cause Each active staff member shall attend 75 percent of staff meetings unless excused by the Executive Committee for just cause"

The new Standard reads

"Active Staff attendance shall average at each meeting at least 50 percent of the active staff who are not excused by the Executive Committee for just cause Each active staff member shall attend 50 percent of staff meetings unless excused by the Executive Committee for just cause"

The modification of this Standard was recommended by the Committee on Standards which was charged by the Board of Commissioners to consider the "Conclusion of the Stover Report"* The Board of Commis sioners voted to accept the recommendation of the Committee on Standards for the following reasons

---

* Staff meetings required by the Joint Commission are acceptable, but the attendance requirement should be set up locally and not by the Commission

1 A well functioning medical staff with good intercommunication is essential to insure quality medical care

2 The general staff meeting is an important tool both as an administrative and educational device to keep the staff as a whole informed of hospital activities and to insure continuity of good medical practice

3 It is essential that every hospital have rules and regulations pertaining to attendance at medical staff meetings In order to make certain that these rules are adequate, the Commission should furnish a specific yardstick in the Standards

Medical staffs and administrators should realize that this new modified Standard supersedes, as of publication in this Bulletin, the former 75 percent attendance requirement The different types of staff meetings or categories to be employed as explained in prior Bulletin No 9 should be reviewed thoroughly The surveyors of the Joint Commission have been instructed to look carefully at the performance of medical staffs as regards review of work performed in the hospital

In Review

Many letters are received each month at the offices of the Joint Commission on Accreditation of Hospitals which show considerable lack of knowledge of the basic structure and program of our organization For informational purposes a few of the facts are reiterated

1 The Joint Commission is a voluntary non-profit organization supported solely by contributions from its member organizations Their names are listed on the mast head No charge is made for a survey of any hospital

2 Before applying for a survey for accreditation a hospital must be eligible The eligibility rules are simple and as follows

a The hospital must have functioned for at least one year in its present capacity

b The hospital must have at least 25 adult beds

c The hospital must be listed by the American Hospital Association For listing, application should be made directly to the American Hospital Association Listing and accreditation are not synonomous, nor are they done simultaneously Listing comes first, then accreditation Any hospital, religious, private, non-profit, governmental or proprietary institution which fulfills the eligibility requirements may apply for accreditation

3 After a hospital applies for accreditation one month to one year may elapse before the hospital can be surveyed Schedules for surveys are made up at least two months in advance and once made usually cannot be changed Hospitals are notified usually two to three weeks in advance of the survey date Because of travel conditions, hospitals in the south generally are surveyed in winter and those in the north in summer

4 After a survey the report is mailed to the office of the Joint Commission by the surveyor or his member organization The surveyor's report contains his written recommendations for the improvement of patient care The staff of the Commission reviews the surveyor's report, any correspondence about the hospital, and the report of the previous survey to determine what action has been taken with respect to the recommendations made The recommendations of the surveyor and the staff are sent to each Commissioner, who approves or disapproves them The hospital is notified of the official action of the Commission The whole process takes from 60 to 90 days If the recommendations are disapproved by even one Commissioner the report to the hospital in question is held over until the Commissioners' meeting, when a vote is taken and a majority prevails

a Hospitals approved for three years are entitled to a Certificate The hospital will automatically be resurveyed in approximately three years

b Hospitals approved for one year are not entitled to a Certificate and must return the previous Certificate if they have one They will be automatically resurveyed in approximately one year

c Hospitals which are not accredited must re-apply for survey if and when they feel that the standards can be met

d Dry runs or trial surveys by the Commission staff cannot be made Neither the money nor personnel is available

e Only physicians are employed to survey hospitals A great deal of an accreditation survey has to do with the quality of care and only a physician can attempt to assess this care

5 The "Standards" of the Joint Commission are its basic document and every hospital medical staff, administrative staff and board of trustees should be acquainted with its contents Bulletins of the Commission are published approximately every four months and contain for the most part interpretations and explanations of the Standards, plus other statistical information

Multiple copies of all basic publications may be purchased for a nominal fee A copy of every Bulletin is sent free to the administrator and the chief of staff of each hospital It is their duty to see that essential information in the Bulletin is passed on to the medical staff and key personnel

6 The primary and controlling purpose of the Joint Commission on Accreditation of Hospitals is to insure that the best possible quality care is provided in hospitals and to encourage improvement of patient care as rapidly as knowledge and experience permits

This purpose is the natural result of the underlying philosophy of the accreditation program The philosophy that hospitals must be evaluated from the point of view of the patient In plain words 'Is this hospital giving good quality care to the extent that I am willing for a member of yours or my family to be a patient in the hospital?"

Accreditation is not compulsory either on the the part of the hospital or the accreditation body It is not licensure It is not government enactment Accreditation is a voluntary effort on the part of every hospital, its medical staff, its board of trustees and its administration to raise the quality of patient care

NATIONAL SCIENCE FAIR

The American Medical Association participated in the eighth National Science Fair in Los Angeles, May 9-11, by presenting citations to the four high school students with the best exhibits in the basic medical sciences The presentations were made at a special A M A banquet for 600 Fair participants—students, advisors, and representatives of organizations sponsoring regional science fairs—Friday evening, May 10, at the Biltmore Hotel Dr Dwight H Murray, A M A President, made the awards and invited the two 'first place" citation winners to be guests of the A M A at its Annual Meeting in New York City, June 3-7 They will display their exhibits in the Scientific Exhibit in the Coliseum

The keynote speaker at the banquet was Dr Wendell M Stanley, professor of biochemistry and director of the virus laboratory at the University of California in Berkeley John Howard, star of "Dr Hudson's Secret Journal," a weekly network television program, was master of ceremonies Entertainment was provided by several Hollywood personalities

The recipients of the A M A citations were selected by a special committee from the Association Committee chairman was Dr Alphonse McMahon, St Louis, Chairman of the A M A Council on Scientific Assembly, and members of the committee were Drs Samuel P Newman, Denver, Stanley P Reimann, Philadelphia, Henry Viets, Brookline, Mass, and Thomas G Hull, Chicago, all members of the Council, and Dr Donald A Charnock, president of the California Medical Association, and Dr J Norman O Neill, president of the Los Angeles County Medical Association

The National Science Fair is the culmination of local and regional science fairs in which finalists from all over the United States compete for national honors It is sponsored by Science Clubs of America to stimulate interest among high school students in the pursuit of science as a career The A M A House of Delegates last June resolved to "bring the whole of organized medicine into active participation in this worthwhile and constructive program to encourage the youth of our nation to take a serious interest in the field of science" During the past two years, a great number of county and state medical societies and their woman's auxiliaries have assisted in the development and promotion of community high school science fairs

A M A SPONSORS MEDICAL CIVIL DEFENSE CONFERENCE

The A M A Council on National Defense has completed program arrangements for its Fifth Annual National Medical Civil Defense Conference, to be held Saturday, June 1, in the Sert Room of the Waldorf-Astoria, New York City The conference is to be devoted to the medical aspects of the hazards and effects of radiation and radioactive fall-out

This is the second such conference held on the topic of radiation hazards, according to Mr Frank W Barton, Council Secretary Several years ago, the A M A Board of Trustees directed the Council to regularly inform physicians about the radiation and radioactive fall-out hazards The first conference devoted to this subject was held in June, 1955, at Atlantic City At hearings conducted by a subcommittee of the House Committee on Government Operations on the subject of civil defense for national survival, Mr Barton said that witnesses of the Naval Radiological Defense Laboratory testified they are convinced, on the basis of their studies, that radioactive fall-out must be considered "the major antipersonnel weapon"

Physicians wishing to attend the conference should make advance registration for the meeting and luncheon by promptly writing to the Council on National Defense, American Medical Association, 535 N Dearborn St, Chicago 10

The Council has arranged for the FCDA to display a radiologic exhibit which will be monitored by Mr Fred Oleson, Radiological Defense Officer, Region I, Federal Civil Defense Administration, Harvard, Massachusetts

Participants

David B Allman, M D, President-Elect, American Medical Association, Atlantic City, N J

James P Cooney, Major General, M C, U S A, Deputy Surgeon General, Department of the Army, Washington, D C

Robert L Corsbie Division of Biology and Medicine, Atomic Energy Commission Washington, D C

Cyril Comar, Ph D, Chief, Biomedical Research, Oak Ridge Institute for Nuclear Studies, Oak Ridge, Tenn

Eugene P Cronkite, M D, Head, Division of Experimental Pathology, Medical Department, Brookhaven National Laboratory, Upton, Long Island, N Y

Cortez F Enloe Jr, M D Member, Committee on Civil Defense Council on National Defense American Medical Association, New York

Jack C Greene Director Radiological Defense Division Health Office, Federal Civil Defense Administration Battle Creek Mich

Honorable Chet Holifield, U S Congressman, 19th District or California, Chairman, Sub committee on Military Operations Committee on Government Operations Washington D C

Joseph W Howland, M D, Chief, Medical Division Atomic Energy Commission Project, University of Rochester, Rochester N Y

Carroll P Hungate, M D, Member, Committee on Civil Defense and Council on National Defense American Medical Association, Kansas City, Mo

Fred Oleson, Radiological Defense Officer, Region I, Federal Civil Defense Administration, Harvard, Massachusetts

Francis B Stewart, Colonel, U S A R, Consultant Chemical and Biological Warfare Defense, Health Office Federal Civil Defense Administration, Battle Creek, Mich

Benjamin C Taylor, Director, Engineering Office, Federal Civil Defense Administration, Battle Creek Mich

M M Van Sandt M D Director, Medical Care Division Health Office, Federal Civil Defense Administration, Battle Creek Mich

INTERNATIONAL ASPECTS OF NEW YORK MEETING

At every Annual Meeting of the American Medical Association there are several hundred physicians from other countries in attendance Never before, however, have so many foreign guests been on the program as there will be in New York this year More than a score of countries will be represented A Trans-Atlantic Medical Conference will be presented for the first time, with a two way telephone connection between London and New York The occasion is the Harvey Tercentenary Congress Sir Clement Price Thomas will head a distinguished panel in the Great Hall at the Royal College of Surgeons, while Dr Michael E DeBakey will be in charge of a similar group in Carnegie Hall, New York Audience participation at both ends will be encouraged The program is presented with the cooperation of Smith, Kline & French Laboratories, Philadelphia

Sir Clement Price Thomas moderator, in London for the Trans-Atlantic Medical Conference

Another first' at the New York meeting will be the International Medical Film Exhibition with four full days of outstanding motion pictures produced in other countries Never before have so many excellent films representing medical progress been gathered together Many of the authors of the films will be present to discuss their work All discussions will be in English The program is presented with the cooperation of Johnson & Johnson, New Brunswick, N J Other leading physicians from abroad will lecture before the sections or present their work in the Scientific Exhibit In addition, more than 2,000 physicians and scientists from the United States will participate in the program, to make the New York meeting an outstanding contribution to graduate medical education

COUNCIL ON MEDICAL SERVICE

ORGANIZED "HOME CARE PROGRAMS" IN THE UNITED STATES

A REPORT BY THE COMMITTEE ON INDIGENT CARE

The concept of care in the home is not a new one Home care has always been an integral part of the practice of medicine in this country, a method whereby the sick person could be attended and relieved of his illness without separation from his family environment

More recently, however, increased attention has been focused on what are being termed "home care programs," in which selected patients who do not require all the treatment facilities of a hospital, but who would otherwise have to be hospitalized, are provided with a range of individualized medical, nursing, social, and rehabilitative services in their own homes, coordinated through one central agency

There has been growing interest in these programs, not just as a substitute for hospital care but as that part of a total medical care plan which can best meet the needs of certain patients or of a given patient in certain phases of his illness It is in view of this increased interest that the Committee on Indigent Care of the Council on Medical Service conducted a survey designed to obtain basic information on the origin and purposes, organization, administrative mechanics, and the advantages and problems encountered in the operation of such home care programs currently under way in the United States

The findings of this survey are reviewed here No effort has been made to evaluate the home care programs now in operation, nor is this report to be considered as either an approval or a disapproval of such programs However, it is believed that the data included here will be helpful to those medical societies concerned with this type of medical care program

The Survey

The Committee's first step was to arrive at a working definition of an organized home care program, as contrasted to those instances in which a patient receives, in his home, the services of a physician who may call individually upon a nurse, a social worker, a therapist, or a homemaker to assist him Background material for this purpose was drawn from the files of the Commission on Chronic Illness, which had compiled many data on the subject, from a survey of 11 home care programs conducted in 1952 by the Public Health Service of the U S Department of Health, Education and Welfare in cooperation with the Commission on Chronic Illness,[1] and from other material in the files of the Committee on Indigent Care

For the purposes of the survey, an organized home care program was defined as "one in which selected patients while homebound are provided with a full range of services which are arranged for and coordinated through one administrative agency or institution, one in which home care, as part of a total medical care plan, meets patients needs during a specific phase, or phases of illness "[2]

A home care program, as such, was expected to include at least the minimum of medical and nursing care, social services, and essential drugs and supplies It was expected that many of the programs surveyed would report additional services, such as physical or occupational therapy, homemaking, health education, and nutritionist services The essential characteristics of an organized home care program were considered to be (1) centralization of responsibility for administration, (2) coordination of the various services and resources made available to the patient, and (3) the development and use of the medical care team or the opportunity for various disciplines to deal jointly with the health needs of the patient and his family and to develop definitive planning for the patient In addition, the program was required to be served by one or more hospitals, with adequate facilities and equipment for extending services into the home[3]

On June 29, 1956, a seven-page questionnaire was mailed to all organizations which had been noted in available literature as having this type of program These organizations were queried as to the origin, purpose, administration, patients served (by types of illness, financial status, and referral sources), number and type of services offered to the patient at home, personnel and administrative mechanics of the program, sources of financing, and advantages and problems encountered in the operation of the program On Aug 13, another copy of the questionnaire was mailed with a follow-up letter to those organizations which had not replied Cut-off date on returns was Sept 30, 1956

From a total of 69 questionnaires mailed, 51 were returned The questionnaire returned by the New York City Department of Hospitals covered the operation of its home care program in 14 municipal hospitals which had been queried individually in the survey Thus 65 of the 69 organizations queried were accounted for in the returns as follows 24 respondees indicated no home care program or that their program had been discontinued, and 27 organizations reported a home care program currently in operation Of these 27 replies, 5 were deleted from the study 3 in which medical care and medicaments only were provided, one in which patients were placed in nursing homes rather than their own homes, and one in which insufficient data were given The remaining 22 programs, in addition to 9 others on which data had been ob

---

Members of the Committee on Indigent Care are Drs John F Burton, Chairman Oklahoma City, A J Bowles, Seattle E P Coleman, Canton, Ill, Wesley W Hall, Reno, Nev I Jay Brightman Albany, N Y, E A Ockuly, Toledo, Ohio, Dean W Roberts Chicago, and Mr R M Hilliard, Consultant Chicago tained for 1951-1952,[1] or a total of 31, are the subject of this report, and are hereafter referred to as the programs (table 1)

Origin and Purposes

At the time of the survey, five programs were operating on a pilot or demonstration basis that is, to demonstrate the practicality of such a program and the degree to which it might meet community needs Three of these programs had been in operation less than a year, one for 14 months, and one for 21 months Three programs were in the process of transition from a demonstration to a continuing basis one of these had been operating for a year, one for three years, and one for four years

One organization, the Boston Dispensary of the New England Medical Center has been providing home care services since 1796 Another organization, the Massachusetts Memorial Hospitals, has been operating a home medical service since 1875 The University of Vermont has operated a home care program since 1925 and the Chicago Department of Welfare has been providing home medical services as part of its over-all assistance program since 1933 Of the remaining 19 programs, one had been in operation for over 15 years, one for over 10 years, 9 for over 5 years, 7 for over 2 years, and one for slightly less than 2 years

There was some variation in the reported objectives and purposes of the various programs, but, with a few exceptions, the objectives seemed to revolve around

† Data in report obtained for year 1951 1952

‡ a medical (visiting physician and/or consultation) b nursing c social service d physical therapy e occupational therapy f speech therapy g health education h housekeeping service i hospital equipment and supplies j medicaments and medical supplies k orthopedic appliances and l transportation

the concept of home care as the most satisfactory means of meeting the total care needs of certain patients or of a patient during certain phases of his illness In the different programs this concept was extended to (1) patients convalescing from acute illness or acute exacerbation of chronic illness, (2) patients too sick or disabled to come to an outpatient clinic but not sufficiently sick or disabled to be in a hospital, (3) chronically ill and/or the indigent who did not require hospital care, (4) patients who were occupying hospital beds solely because a more suitable place for care was lacking, and (5) patients whose psychological and emotional needs would be more readily met, with recovery made more quickly, if their family environment could be maintained

Only one of the programs was established primarily as a teaching experience for medical and other student personnel, but eight of the sponsoring organizations reported this activity as one of the purposes or part of the current operation of the program Without exception, the organizations including professional or student education in their program cited the excellence of home care as a teaching experience in the family setting

Some of the programs were established primarily to offset a shortage of hospital beds, as an alternative to the high cost of hospital care for the indigent and medically indigent, and for other specific reasons However, there was a growing acceptance throughout the survey returns of home care not just as a way to save money or as a substitute for hospital care or as a new way of training professional personnel but as the best means of providing for medical, social, and rehabilitative needs of certain patients or of an individual patient during certain phases of his illness, and as an important part of a total medical care plan for certain groups

In general, then, the somewhat overlapping objectives, cited by the founding organizations, in establishing a home care program were (1) to provide the indigent and medically indigent with a quality of care and a range of services not normally available to this group, and at less cost, (2) to shorten the length of stay of hospital patients and reduce the readmission of discharged patients by providing better follow-up care at home, (3) to bridge the gap in medical care for those patients too ill to visit an outpatient clinic but who do not need hospital care, (4) to meet the needs of a growing number of chronically ill and/or aged patients who do not require institutional care but are occupying institutional beds because a more suitable place for care is lacking, (5) to speed the recovery of those patients to whom the family environment would have a therapeutic effect, (6) to offer the homebound patient a coordinated spectrum of medical, social, and rehabilitative services individualized to his particular needs, (7) to afford medical, nursing, and other professional and student personnel with a teaching experience in environmental medicine, and (8) to provide the private family physician with a single source from which he can obtain a comprehensive array of nursing, social, and rehabilitative services for his patient

In all of the programs studied, including those on a demonstration basis, the sponsoring organizations felt that the original purposes of the program had been or were in the process of being fulfilled

Administration and Organization

In one program operating on a pilot basis at th time of the survery, the administrative and coordinative duties were carried on by an independent committee which was created specifically for that purpose and which did not itself provide any direct service to patients In this program, administrative responsibility was delegated to an executive committee composed of representatives from the county medica society and six other local health, welfare, and servic organizations This committee worked with a medica advisory board consisting of representatives from si medical specialties in determining medical policies

In all of the remaining programs the administrativ agency participated to some extent in direct services t patients This participation varied from a hospita based program in which the administrative agenc provided 11 of 13 different home services, to a progra administered by a private social agency which provid ed only social casework services and arranged for 1 other patient services through existing communit facilities Thirteen of the remaining 30 programs wer administered by general hospitals or by department of general hospitals One of these was established as separate entity but was based at a general hospita insofar as the director of the hospital was also th director of the home care program and the hospit provided some of the patient services

One program was administered jointly by a genera hospital and a chronic disease unit Four were administered jointly by a medical school and a general hospital, three by chronic disease hospitals, and one b a university medical school Three programs were administered by visiting nurse associations In two o these, administrative and coordinating responsibilitie were delegated to the director of the visiting nurs association, who set up over-all program policie under the guidance of a steering committee and wit the help of a medical coordinator In the third program, administrative responsibility was vested in public health nurse coordinator who worked full tim on the program under a board of directors and wit the guidance of a medical advisory committee and professional advisory committee in setting progra policies

Three programs were administered by health departments one by a public health department in clos affiliation with a municipal hospital, one by a cit health department in cooperation with a state medica college, and one by a county health department as part of its over-all health program

In two other organizations also, home services wer given only as a part of an over-all health progra One of these programs was administered by a cit welfare department as part of its over-all general assistance program to city indigents The other was carried on by a private social agency as one facet of it over-all health assistance program for needy olde people Table 2 gives a brief description of the administrative organization in all programs

TABLE 2—*Administrative Agency—All Programs*

(1) Administered by the Alameda County (Calif) Department of Institutions—based at the Fairmont Hospital of Alameda County a chronic disease hospital

(2) Established as a separate entity but based at the Mt Zion Hospital a voluntary nonprofit general hospital insofar as the director of the program is also director of the hospital and some of the patient services emanate from the hospital Program maintains a close though informal working relationship with Chronic Illness Service Center and other service groups in San Francisco

(3) Administered jointly by the University of Colorado Medical School and the Denver Department of Health and Hospitals Based at the General Medical Clinic of Denver General Hospital Home care services provided as part of over all educational service program to Denver indigents n hospital home or outpatient clinic

(4) Established as a separate entity and administered by an executive committee composed of a physician-chairman who is medical administrator of the program and representatives from the Hartford County Medical Association City Health Department Visiting Nurse Association Hartford Rehabilitation Center Family Service Society Junior Chamber of Commerce and social service departments of local hospitals

(5) Administered by the Bureau of Disease Control of the D C Department of Public Health and based at the D C General Hospital

(6) Administered by the Georgetown University Hospital a church affiliated general hospital in Washington in cooperation with the Georgetown University School of Medicine

(7) Administered by and based at the Mt Sinai Hospital a voluntary nonprofit general hospital in Chicago

(8) Administered by and based at the Mercy Clinics of Mercy Hospital Chicago a church affiliated general hospital connected with the Stritch School of Medicine of Loyola University

(9) Administered by the Babette and Emmanuel Clinic of Michael Reese Hospital a voluntary nonprofit general hospital

(10) Administered by th Chicago Department of Welfare Home care services are given when needed as part of the department s over all assistance program to the indigent of the city

(11) Administered by the Visiting Nurse Association in Peoria under the guidance of a medical advisory committee and a professional advisory committee Program functions essentially as a separate entity

(12) Administered by the Boston Dispensary which with the Floating Hospital and the Tufts Medical School makes up the nucleus of the New England Medical Center which provides clinical experience to Tufts College medical students

(13) Administered jointly by the Massachusetts Memorial Hospitals a voluntary nonprofit association and the Boston University School of Medicine which is privately endowed

(14) Administered by the Beth Israel Hospital a voluntary nonprofit general hospital in Boston

(15) Administered by the Visiting Nurse Association in Detroit under the guidance of a steering committee that includes members of the Wayne County Medical Society

(16) Administered by St Mary s Hospital of Rochester a church affiliated general hospital

(17) Administered by the Jewish Hospital of St Louis a voluntary nonprofit general hospital which comprises a part of the Jewish Hospital Center in St Louis The program operates as a specific department of the hospital

(18) Administered by the Mountainside Hospital a voluntary nonprofit general hospital serving Montclair and 10 other communities in Essex County

(19) Administered by the New York City Department of Hospitals and operated in 15 city hospitals 13 general 2 chronic and one tuberculosis hospital

(20) Administered by the Montefiore Hospital a voluntary nonprofit hospital fo chronic disease

(21) Administered by the Bronx Hospital a voluntary nonprofit general hospita

(22) Administered by the Home for Aged and Infirm Hebrews a voluntary nonprofit chronic disease hospital

(23) Administered by the Genesee County Health Department as part of its over all health program and in cooperation with the Genesee Memorial Hospital

(24) Administered by the Jewish Hospital of Cincinnati a voluntary nonprofit general hospital

(25) Administered by the Benjamin Rose Institute a private social agency which was set up through a trust fund for the care of older people Home care services are given when needed as part of the Institute s total program of assistance to needy older people

(26) Administered by the Visiting Nurse Society in Philadelphia under the guidance of a steering committee composed of a part time medical consultant and representatives from civic and professional groups

(27) Administered by the Montefiore Hospital in Pittsburgh a voluntary nonprofit general hospital

(28) Administered jointly by the Albert Einstein Medical Center in Philadelphia a voluntary nonprofit general hospital and the Lucien Moss Home a nonprofit voluntary chronic disease facility which is physically contiguous with the Northern Division of the Medical Center

(29) Administered by the University of Vermont School of Medicine and jointly financed by the School and the City of Burlington

(30) Administered by the Richmond Va Department of Public Health Program operates in close cooperation with the Medical College of Virginia which provides some of the patient services and uses the program as a teaching resource

(31) Administered by the King County (Seattle) Hospital System consisting of two county hospitals University of Washington School of Medicine uses the program as a teaching resource for medical students

Private Physician Participation

In six of the programs, patients were required to have a private physician willing to assume responsibility for their care before they could be admitted to the home care program The various services and facilities in the program were then coordinated to the request of the individual physician, who decided which services his patient would receive, either alone or after consultation with the medical and professional advisors on the program If the patient had no private physician at the time of referral to the home care program, he was required to select one from among the practicing physicians in the community

Three of these private physician-based programs were on a pilot basis at the time of the survey, this included the program which was administered independently of the service-providing agencies and two of the programs administered by visiting nurse associations The fourth program was in the process of transition from a pilot to a continuing basis, and was administered jointly by a general hospital and a chronic disease unit The fifth program had been operating since 1949, and was also administered by a visiting nurse society The sixth program was administered by a county health department as part of its over-all health program

Four of these programs were restricted to patients with long-term illness, and two accepted patients with both chronic and acute diseases All provided services both to the indigent and to patients able to pay, with the latter charged according to their ability to pay

Two other programs also provided the patient with a free choice of physician, but in a slightly more restricted sense In one of these, administered by a county chronic disease hospital and serving indigent and medically indigent tuberculosis patients only, the patient selected his physician from a panel maintained by the program This physician then became responsible for the patient s total treatment and ordered such services as he thought necessary In the second program, administered by a city department of welfare as part of its over-all assistance program to the indigent, the patient selected a physician from a roster of approximately 1,000 licensed physicians who had expressed a desire to participate in the program These physicians prescribed such services as they thought necessary for their patients, in consultation with a medical advisory committee, and were paid by the program for medical services on a fee-for-service basis

In seven of the programs the patient remained under the care of his private physician if he had one, although this was not one of the requirements for eligibility If the patient had no private physician, he was treated by a physician on the home care staff or panel

In 15 of the programs patients received medical services only from physicians on the home care staff or medical students participating in the program, who prescribed additional services to the patient as needed, alone or in joint consultation with other members of the home care team Ten of these programs were hospital-based, three were administered jointly by a hospital and medical school, one by a medical school only, and two by city health departments

One other hospital-based program, which was established originally for the indigent and medically indigent, also attempted on a pilot basis to care for private patients, retaining the patient's family physician as head of the medical care team However, the project was discontinued because payments by Blue Cross and Blue Shield could not be made applicable to care in the home Table 3 shows the sources of medical services to patients for all programs

TABLE 3 —*Sources of Medical Services to Patients—All Programs*

Source of Care	Program Numbers
Home care physicians only	(1)* (2) (3) (5) (7) (8) (9) (10)* (12) (13) (14) (18) (19) (20) (24) (27) (30) (31)
Private physicians or home care physicians	(6) (16) (17) (21) (22) (25) (29)
Private physicians only	(4) (11) (15) (23) (26) (28)

* Selected by the patient from a panel or roster of physicians maintained by the home care program

Two of the programs in which the patient could receive home medical services only from physicians on the program staff reported some difficulty in interpreting the program to private physicians in the community and a reluctance on the part of these physicians to transfer responsibility for their patients care

Types of Patients

Of the 31 programs, 19 were restricted to indigent and medically indigent patients, of these, 8 served only patients with long-term illness, 11 accepted those with both acute and chronic diseases, and one accepted only tuberculosis patients

In 12 programs, home services were available to both indigent or medically indigent and paying patients, who were charged according to their ability to pay Five of these programs were restricted to persons with chronic diseases, five accepted those with both chronic and acute cases, and two were restricted to cancer patients In five of these programs, indigency was not specifically stated as a requirement for admission, but the majority of the patient case load were indigent or medically indigent, and the program was oriented primarily toward serving this group Table 4 shows the type of patients served, by financial status, for all programs

A number of programs specified exceptions within the disease categories accepted for care Most frequently mentioned was mental illness, which was excepted from eligibility in eight of the programs Active tuberculosis was not accepted in five of the programs, obstetric cases were not accepted in two programs, one program would not accept patients with diabetes, and two would not accept patients with contagious diseases Table 5 shows the general disease categories eligible for care in all programs

TABLE 4 —*Type of Patients Served, by Financial Status, for All Programs*

Type of Patients	Program Numbers
Indigent and medically indigent only	(1) (2) (3) (5) (7) (8) (9) (10) (12) (13) (14) (18) (19) (20) (24) (27) (29) (30) (31)
Indigent and paying but actual case load primarily indigent	(6) (16) (21) (25) (28)
Indigent and paying	(4) (11) (15) (17) (22) (23) (26)

The following additional criteria for patient eligibility were common to most of the programs 1 The patient's illness must be of a type medically suitable for home care, i e, the patient does not need the intensive diagnostic and treatment services of a hospital but needs medical supervision, is too ill to obtain it on an ambulatory basis, and the illness can be adequately cared for in the home without constituting a medical hazard to the rest of the family 2 The patient's home must be physically suitable for care 3 There must be a family member or other person available to care for the patient at home 4 The patient must desire to remain at home, and home environment should be psychologically suitable 5 The family must want the patient at home, and his presence must not impose undue hardship on other family members

Almost all of the programs limited their home care services to those patients living within a specified geographical area, for such reasons as staff travel time and expenses, the accessibility to the patient of the central home care agency, and the administrative jurisdiction of the sponsoring agency The distances to which home care services were extended in the various programs varied from 3 to 15 miles, and would indicate a probable practical limit of about 20 miles or an hour's travel time one way

In one program, administered by a private social agency as part of an over-all assistance program to the elderly, only men over 65 and women over 60 years of age, of Anglo-Saxon origin, were eligible for services In two programs, patients were required to be of Jewish faith

TABLE 5 —*General Disease Categories Eligible for Care—All Programs*

Categories	Program Numbers
Chronic only	(2) (5) (7) (9) (11) (14) (16) (20) ([illegible]) (24) (26) (27) (28)
Chronic and acute	(3) (4) (8) (10) (12) (13) (15) (17) (18) (19) (23) (25) (29) (30) (31)
Specific disease categories only	(1) (6) (21)

Referral Sources

Eleven hospital-based programs accepted patients primarily or solely from wards or the outpatient clinic of the hospital or from affiliated social agencies in one case One of the programs which was private physician-based accepted referrals only from physicians in the community, another accepted referrals primarily from this source

Eighteen programs accepted referrals from any agency or individual in the community In this last group, hospital wards and outpatient clinics constituted an important referral source, whether they were part of the administrative agency in hospital-based programs or under other hospitals in the community Other important referral sources included physicians, patients and families or relatives, nursing and convalescent homes, visiting nurse associations, and various social, health, and welfare agencies in the community

The number of patients receiving services during a year's time varied from 3 patients in one of the pilot programs which had been in operation for about two months at the time of the survey to 8,868 patients in the Boston Dispensary program which had been in operation since 1796 Four programs besides the Boston Dispensary had a yearly case load over 1,000

In the five programs operating on a pilot basis, the patient case loads were comparatively small, ranging from 3 to 56 Most of the remaining programs clus tered in a range of between 25 and 100 patients served per year, with a fairly even distribution between these two points

Services to Patients

In this survey, the organizations queried were not asked to describe specifically the services given to the patient in his home other than under headings such as "medical,' "nursing," and 'social" However, using descriptions of this type that were obtained in a previous detailed survey of 11 home care programs,[1] and certain other data obtained in the present survey, it may be of practical value to attempt a description of the specific procedures that such things as home medical services and nursing services might entail

On the basis of previous information, home medical services may include such procedures as taking case histories, making physical examinations and diagnoses, dispensing and administering routine medicaments given orally or parenterally, taking blood, urine, or sputum specimens for analysis, and other uncomplicated diagnostic and therapeutic procedures, including, in some cases, electrocardiography, determinations of basal metabolic rates, transfusions, and, in some cases, minor surgical procedures and specialist consultation

Nursing services may include such services ordered by the physician as dressings, injections and irrigations, assisting the physician with such therapeutic procedures as transfusions and surgical procedures, bed baths and other personal care, health instruction to the patient, and teaching other members of the family how to care for the patient

Social services may include evaluation of the patient s social eligibility for home care, interpretation of the program to patients and family members, helping the family adjust themselves to illness in the home, utilizing community resources to meet family economic needs and social problems not directly related to the illness situation, and maintaining liaison between and coordination of the various other agencies providing home care services

Physical therapy would include such services as corrective exercise, massage, short wave and ultraviolet treatments, wax therapy, instruction in crutch walking and the use of other prosthetic appliances, and chiropodic care for diabetic patients

Occupational therapy would include such activities as leather work, basket making, painting, weaving, music and the learning of specific skills and crafts, and would encompass both diversional and occupational therapy

Speech therapy would include visits as needed by a qualified speech therapist

Health education may include instruction of the family in caring for the patient, instruction of the patient in personal care, nutritional and meal planning consultation, especially for patients with diabetes, and other related services, usually carried on by a nurse, nutritionist, or social worker

Homemaker services would include the preparation of meals and menu planning, care of children in the home, marketing, and other domestic work necessary to maintain the home

Other services which may be provided in a home care program include home teaching for children on the program, medicaments and medical supplies, orthopedic appliances, psychological testing and psychiatric consultation, oxygen and blood, hospital equipment and supplies, and transportation of the patients, supplies and equipment, or the home care staff

Medical and nursing services were provided in all 31 programs, as were social services Some form of therapy was provided in 27 of the programs 11 provided all three—physical, occupational, and speech, 7 provided occupational and physical therapy, one provided physical and speech therapy, one provided occupational therapy only, and 7 provided physical therapy only

Medicaments and medical supplies were provided in all programs but two Homemaker service was provided in 28 of the programs, health education in 27 hospital equipment and supplies in 30 and orthopedic appliances in 30 of the programs

Additional services provided included teaching for home-bound children in three programs, psychological testing in one program, vocational counseling in one program, and provision for transfer of patients in terminal condition to a nursing home in one program serving cancer patients only (table 6)

Financing

The costs of providing home care were paid for through a variety of sources, which included (1) "allocations drawn from the budget of the administrative agency , (2) grants given directly to the program from voluntary or philanthropic agencies or organizations, to be used as the administrators of the program saw fit, (3) grants earmarked by the contributing organizations for specific items on the home care budget such as salaries or certain services, (4) payments to the home care programs by welfare departments and other public assistance agencies on behalf of specific patients, (5) services provided and paid for by other community agencies participating in the program, such as visiting nurse services, (6) payments from patients and families for services received, and (7) (notably in those programs administered by public agencies) tax monies allocated from the budget of the political subdivision under which the program operated

Nine programs were administered by public agencies or institutions Seven of these were supported primarily by tax funds, either drawn from the budget of the administrative agency or allocated from the total budget of the political subdivision under which the agency operated In the other two programs, approximately two-thirds of the budget was derived from tax funds, with the remainder being paid through grants from a private foundation Three of these programs also used services, facilities, space, etc, furnished from other community resources, which were not charged to the home care budget

In only one of the publicly administered programs did patients defray any of the costs of home care in the year for which data were obtained This was one of the programs in which patients remained under the care of their private physician if one was available, and patient payments consisted primarily of fees for medical services

The remaining 22 programs were administered by various private agencies or organizations In all except one of these programs, endowments and grants from voluntary and philanthropic agencies constituted an important, and in many cases the primary, source of outside funds The exception was a church-affiliated hospital which provided home care as a charity service to patients and met all costs through the hospital budget. In 11 of the privately administered programs, patients or their families made some payments for services rendered, but with one or two exceptions these payments were small, and comprised a relatively minor part of the total sources of funds Some of the programs received some payment from public welfare or assistance agencies on behalf of specific patients The amount varied from a very small portion to over approximately one-fourth of the total sources of funds in the various programs Many of the privately administered programs used services, facilities, personnel, etc, from other community resources, provided without charge to the home care budget In many cases, the monetary value of these services had not been calculated, but, in cases where value was mentioned, the amounts ranged from 5 to 12% of the total costs of home care

The total costs of the home care programs can be divided into four major categories (1) costs paid by the home care budget or administrative agency (monies used here may be allocations from the budget of the administrative agency, grants from private or philanthropic agencies, or tax funds allocated to those programs administered by public agencies), (2) costs paid by public welfare or assistance agencies on behalf of specific patients, and costs paid by public or tax-supported agencies providing services in the program, (3) costs paid by private or voluntary agencies providing services in the program, and (4) costs paid by patients

or families or by private insurance owned by patients Table 7 shows the sources of payment for direct services to patients, divided according to these four categories, for all programs, and also the sources of payment for salaries of personnel on the home care staff The total yearly cost of operating the program was not specified in all of the replies, but, where it was, the figures ranged from $2,700 to $95,500

There did not seem to be any direct relation between the total cost of the program and the number of patients served For instance, one program which served just over 40 patients during the year cited an approximate total cost of $3,000, while another program with this same case load spent approximately $16,700, more than five times as much However, certain data that were not obtained in the survey, such as the average number of home visits per patient, or the total number of patient visits, would probably show a more consistent relationship between these two factors, and make possible a more valid comparison of the variations in cost between the different programs

MEDICINE AND THE LAW

This is the 10th in a series of articles dealing with medical professional liability An editorial (page 360) and a chronological résumé (page 364) appeared in The Journal, *Feb 2 One of the preceding articles in this series has been published each week in* The Journal *beginning Feb 9, 1957, except in the April 13, April 20, April 27, and May 4 issues* —Ed

STATE REGULATION OF PROFESSIONAL LIABILITY INSURANCE RATES

Prior to about 10 years ago, there was almost no rate regulation by state insurance supervisory authorities of medical professional liability insurance premiums In fact, this type of insurance still represents a very small percentage of the total amount of casualty insurance premiums written As a result of this absence of state regulation, each individual company was at liberty to determine its own rates However, the National Bureau of Casualty Underwriters assumed jurisdiction in rate promulgation and risk classification on behalf of member insurance companies, effective Sept 1, 1952 When companies announced that medical professional liability insurance rates were to be increased in some states, many physicians concluded that they were being taken and that the announced increases were simply the result of concerted action motivated by selfish interests on the part of the underwriters Studies have indicated that this was not a justifiable conclusion

State Control of Insurance Rates

State	Origin of Power		Exercise of power			States in Which Pending or Existing Legislation Relates to Professional Liability Insurance

In June of 1945, the Supreme Court of the United States, for the first time, ruled insurance to be interstate commerce and subject to the federal antitrust law The following year, Congress enacted a measure (P L 15, 79th Congress) reaffirming the traditional right of regulation to the states and stipulating that the federal government would assume jurisdiction only to the extent that the business was not regulated by the state supervisory authorities In addition, P L 15 contained a moratorium allowing the states, where necessary, a period of two years in which to adopt statutes that would provide uniform elements of regulation

As part of a study of medical professional liability, the Council on Medical Service and the Law Department have surveyed the extent to which the several states fix or control insurance rates The study, which revealed the existence of regulatory laws in almost all of the states, was carried out by means of a questionnaire that was mailed to the insurance departments of the 48 states and the District of Columbia

The primary purpose of the questionnaire was to determine whether or not there were specific laws on the subject in the respective jurisdictions A secondary purpose was to learn how the states administered the statutory or implied authority of rate regulation, such as whether the insurance department, by whatever name known, actually fixed rates for all types of casualty insurance or merely exercised control over them by approving or disapproving rate schedules prepared either by the insurance companies or designated rating organizations A response was received from every state and the District of Columbia, and the results, while not unanimous, were certainly conclusive

Forty-three states and the District of Columbia indicated that their laws contain specific statutory authority to control or regulate rates for professional liability insurance (see table) Thirteen of the 43 states reported that their laws contain both specific and implied authority One additional state indicated that its laws contain only implied authority to do so

Forty-three states and the District of Columbia indicated that their insurance departments did not, themselves or through a delegated authority, fix rates The respondents stated that they did process and approve or disapprove rates filed by insurers or designated rating organizations, such as Mutual Insurance Rating Bureau, National Bureau of Casualty Underwriters, and National Insurance Rating Bureau Nine of these 43 states said that they also fix rates themselves, either by the department directly or through a delegated authority

MEDICAL NEWS

CALIFORNIA

Los Angeles Art Exhibit —The annual exhibition of the Los Angeles Physicians' Art Society will be held May 29-June 28 in the Los Angeles County Medical Association Auditorium Only paid members may participate and only two pieces may be submitted by an exhibitor All work must be in by 5 p m , May 24 A hanging charge of $2 50 will be made for each piece

Information may be obtained by telephoning Virginia Bown, Executive Secretary, at NOrmandy 3-1062

Personal —Dr Robert W Noyes, assistant professor of obstetrics and gynecology, Stanford University School of Medicine, Stanford University-San Francisco, John and Mary R Markle Scholar, will spend his sabbatical year doing research at Cambridge University, England ——Dr J Joseph Quilligan Jr , associate professor of pediatrics, College of Medical Evangelists School of Medicine, Los Angeles, recently received from the U S Army a $13,671 grant for the purpose of studying ways to improve influenza vaccine for children

DISTRICT OF COLUMBIA

Personal —Dr Mario Mollari, chairman of bacteriology and immunology, Georgetown University Medical Center, Washington, D C , has been elected vice-president of the International Society for the Study of Infectious Diseases, Parasitology, and Immunology —— Dr Daniel Leo Finucane has been appointed director of the District of Columbia Health Department, succeeding Dr Daniel L Seckinger, who retired Jan 31 Dr Finucane has been superintendent and medical director of Glenn Dale Sanatorium since 1939 —— Dr Basil Blumenthal has been appointed director of the outpatient department at Georgetown University Hospital Dr Blumenthal, clinical associate professor of medicine at the university s school of medicine, has been associated with Georgetown since 1947

Medical Art on Tour —A unique collection of medical art by Rembrandt, Daumier, Hogarth, Toulouse-Lautrec, and other masters was exhibited at the Georgetown University School of Medicine recently The collection, entitled, "Ars Medica," or the healing arts, was composed of 85 pieces of graphic art depicting the practice of medicine over the centuries Owned by the Philadelphia Museum of Art, the exhibition is being presented on a cross-country tour by Smith, Kline and French Laboratories, under whose grant the collection was assembled The scope of the show extends from medical illustrations designed for teaching purposes—such as those of Vesalius, Wechtlin, and others—to portrayals and critiques of medical procedures of the past Assembled by Carl Zigrosser, curator of prints at the Philadelphia Museum, it is being displayed in mobile units which are especially designed for purposes of the current tour

ILLINOIS

Dr Baer Honored —Dr Walter H Baer, of Peoria, was guest of honor at a testimonial dinner sponsored recently by the Peoria Mental Health Society His fellow psychiatrists, townsmen, and friends from other parts of the country, gathered to salute Dr Baer's contributions to mental health in his community, state, and nation, including his work on the Joint Commission on Mental Illness and Health The principal speaker was Dr Jack R Ewalt, director of the joint commission and, like Dr Baer, one of its founders

Chicago

Cardiac Conference —The cardiovascular committee of the Cook County Hospital announces a conference May 21, 11 a m , at the Children's Amphitheater, 700 S Wood St Dr Aldo A Luisada, director, department of cardiology, Chicago Medical School, will speak on 'Recent Advance in phonocardiography of the Normal and Abnormal Heart " Physicians are invited
